# Working Draft, C++ extensions for Ranges

Note: this is an early draft. It's known to be incomplet and incorrekt, and it has lots of bad formatting.

List of Figures v

## 1 General [intro]

Naturally the villagers were intrigued and soon a fire was put to the town's greatest kettle as the soldiers dropped in three smooth stones.

"Now this will be a fine soup", said the second soldier; "but a pinch of salt and some parsley would make it wonderful!"

—Author Unknown

1.1 Scope [intro.scope]

- <sup>1</sup> This Technical Specification describes extensions to the C++ Programming Language 1.2 that permit operations on ranges of data. These extensions include changes and additions to the existing library facilities as well as the extension of some core language facilities. In particular, changes and extensions to the Standard Library include:
- $^{(1.1)}$  The reformulation of the foundational and iterator concept requirements using the syntax of the Concepts TS 1.2.
- (1.2) The respecification of the Standard Library algorithms in terms of the new concepts.
- (1.3) The loosening of the algorithm constraints to permit the use of *sentinels* to denote the end of a range and corresponding changes to algorithm return types where necessary.
- (1.4) The addition of new concepts describing *iterable* and *range* abstractions; that is, objects with a begin iterator and an end sentinel.
- (1.5) The addition of new overloads of the Standard Library algorithms that take iterable objects.
- (1.6) Support of callable objects (as opposed to function objects) as arguments to the higher-order algorithms.
- (1.7) The addition of optional *projection* arguments to the algorithms to permit on-the-fly data transformations.
- (1.8) Changes to existing iterator primitives and new primitives in support of the addition of sentinels to the library.
- (1.9) Changes to the existing iterator adaptors and stream iterators to make them model the new iterator concepts.
- (1.10) New iterator adaptors (counted\_iterator and common\_iterator) and sentinels (unreachable).
  - <sup>2</sup> Changes to the core language include:
- (2.1) the extension of the range-based for statement to support the new iterator range requirements (24.11).
  - <sup>3</sup> This paper is based on the design presented in "Ranges for the Standard Library, Revision 1" (1.2). Refer to that document for a discussion of motivations and design trade-offs.
  - <sup>4</sup> The scope of this paper does not yet extend to the other parts of the Standard Library that need to change because of the addition of concepts to the langauge (e.g., the numeric algorithms), nor does it add range support to all the places that could benefit from it (e.g., the containers).
  - <sup>5</sup> This paper does not specify any new range views, actions, or facade or adaptor utilities. See the Future Work appendix (C).

§ 1.1

The International Standard, ISO/IEC 14882, provides important context and specification for this paper. This document is written as a set of changes against that specification. Instructions to modify or add paragraphs are written as explicit instructions. Modifications made directly to existing text from the International Standard use underlining to represent added text and strikethrough to represent deleted text.

Text in underline is used to denote text that was added since N4382, and strikethrough denotes text removed.

#### 1.2 Normative references

[intro.refs]

- <sup>1</sup> The following referenced documents are indispensable for the application of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.
- (1.1) ISO/IEC 14882:2014, Programming Languages C++
- (1.2) JTC1/SC22/WG21 N4377, Technical Specification C++ Extensions for Concepts
- (1.3) JTC1/SC22/WG21 N4128, Ranges for the Standard Library, Revision 1
- (1.4) JTC1/SC22/WG21 N3351, A Concept Design for the STL

ISO/IEC 14882:2014 is herein called the *C++ Standard*, N3351 is called the "The Palo Alto" report, and N4377 is called the Concepts TS.

#### 1.3 Implementation compliance

[intro.compliance]

<sup>1</sup> Conformance requirements for this specification are the same as those defined in 1.3 in the C++ Standard. [Note: Conformance is defined in terms of the behavior of programs. —end note]

#### 1.4 Acknowledgments

[intro.ack]

<sup>1</sup> The design of this specification is based, in part, on a concept specification of the algorithms part of the C++ standard library, known as "The Palo Alto" report (1.2), which was developed by a large group of experts as a test of the expressive power of the idea of concepts.

§ 1.4 2

### 6 Statements

## $[\mathbf{stmt}]$

#### 6.5 Iteration statements

1

(1.1)

[stmt.iter]

#### 6.5.4 The range-based for statement

[stmt.ranged]

[Editor's note: Modify paragraph 1 to allow differently typed begin and end iterators.]

For a range-based for statement of the form

for ( for-range-declaration : expression ) statement let range-init be equivalent to the expression surrounded by parentheses

( expression )

and for a range-based for statement of the form

for (for-range-declaration: braced-init-list) statement

let range-init be equivalent to the braced-init-list. In each case, a range-based for statement is equivalent to

```
{
 auto && __range = range-init;
 for ( auto __begin = begin-expr,
             __end = end-expr;
        __begin != __end;
        ++__begin ) {
   for-range-declaration = *__begin;
    statement
}
 auto && __range = range-init;
 auto __begin = begin-expr;
 auto __end = end-expr;
 for ( ; __begin != __end; ++__begin ) {
    for-range-declaration = *__begin;
    statement
 }
}
```

where \_\_range, \_\_begin, and \_\_end are variables defined for exposition only, and \_RangeT is the type of the expression, and begin-expr and end-expr are determined as follows:

- if \_RangeT is an array type, begin-expr and end-expr are \_\_range and \_\_range + \_\_bound, respectively, where \_\_bound is the array bound. If \_RangeT is an array of unknown size or an array of incomplete type, the program is ill-formed;
- if \_RangeT is a class type, the *unqualified-ids* begin and end are looked up in the scope of class \_RangeT as if by class member access lookup (3.4.5), and if either (or both) finds at least one declaration, *begin-expr* and *end-expr* are \_\_range.begin() and \_\_range.end(), respectively;
- (1.3) otherwise, begin-expr and end-expr are begin(\_\_range) and end(\_\_range), respectively, where begin and end are looked up in the associated namespaces (3.4.2). [Note: Ordinary unqualified lookup (3.4.1) is not performed. end note]

§ 6.5.4

```
[Example:
  int array[5] = { 1, 2, 3, 4, 5 };
  for (int& x : array)
      x *= 2;
--end example]
```

§ 6.5.4 4

### 19 Concepts library

## [concepts.lib]

#### 19.1 General

[concepts.lib.general]

This Clause describes library components that C++ programs may use to perform compile-time validation of template parameters and perform function dispatch based on properties of types.

<sup>2</sup> The following subclauses describe core language concepts, foundational concepts, function concepts, iterator concepts, and rearrangement concepts as summarized in Table 1.

Table 1 — Fundamental concepts library summary

	Subclause	Header(s)
19.2	Core language concepts	<concepts></concepts>
19.3	Foundational concepts	
19.4	Function concepts	

- 3 In this Clause, CamelCase identifiers ending with "Type" denote template aliases.
- <sup>4</sup> A regular function is a function that returns equal output when passed equal input. A regular function that returns a value may copy or move the returned object, or may return a reference. Regular functions are allowed to have side effects and preconditions that, when violated, make the function non-regular. [Note: A function that returns void is necessarily a regular function. end note]

#### 19.2 Core language concepts

[concepts.lib.corelang]

#### 19.2.1 In general

1

[concepts.lib.corelang.general]

<sup>1</sup> This section contains the definition of concepts corresponding to language features. These concepts express relationships between types, type classifications, and fundamental type properties.

#### 19.2.2 Concept Same

[concepts.lib.corelang.same]

```
template <class T, class U>
concept bool Same = see below;
```

- The Same concept is used when requiring that two types are the same.
- Same<T, U> is an alias for true when T and U denote the same timetype after the elimination of aliases; otherwise, it is an alias for false. Same<T, U> shall have the same value as is\_same<T, U> ::value.
- Remarks: For the purposes of constraint checking, Same<T, U> implies Same<U, T>.

#### 19.2.3 Concept Derived

[concepts.lib.corelang.derived]

```
template <class T, class U>
concept bool Derived = see below;
```

The Derived concept is used when requiring that a type T is derived from U, or the same type as UDerived<T, U> has the same value as is base of<U, T>::value.

#### 19.2.4 Concept Convertible

[concepts.lib.corelang.convertible]

```
template <class T, class U>
concept bool Convertible = see below;
```

The Convertible concept concept expresses the requirement that a type T can be implicitly converted to type UConvertible<T, U> has the same value as is\_convertible<T, U>::value.

#### 19.2.5 Concept Common

#### [concepts.lib.corelang.common]

Two types T and U are unambiguously convertible if there exists a unique, explicit conversion from T to U, or from U to T, but not both. [Note: This is trivially true when T and U are the same type since no conversion would be required.—end note]

<sup>2</sup> If T and U can both be <u>unambiguouslyexplicitly</u> converted to a third type, C, <u>then</u> T and U share a *common type*, C. [*Note:* C could be the same as T, or U, or it could be a different type. — *end note*] This notion is encapsulated by the CommonType alias and the Common concept.

```
template <class T, class U>
using CommonType = common_type_t<T, U>;

template <class T, class U>
concept bool Common =
   requires (T t, U u) {
    typename CommonType<T, U>;
    typename CommonType<U, T>;
    requires Same<CommonType<U, T>, CommonType<T, U>;
    {CommonType<T, U>{(forward<T>(t))}};
   {CommonType<T, U>{(forward<U>(u))}};
};
```

- Two types T and U model the Common concept when the type alias CommonType<T, U> is well-formed, and when objects of types T and U can be explicitly converted to the common type.
- Let C be CommonType<T, U>. Let t1 and t2 be objects of type T. t1 equals t2 if and only if C{(t1}) equals C{(t2}). Let u1 and u2 be object of type U. u1 equals u2 if and only if C{(u1}) equals C{(u2}).
- [Note: Users are free to specialize common\_type when at least one parameter is a user-defined type. Those specializations are considered by the Common concept. end note]

#### 19.2.6 Concept Boolean

[concepts.lib.corelang.boolean]

```
template <class B>
concept bool Boolean =
  requires(B b1, B b2) {
    {-bool(b1)-};
    { b1 } -> bool;
    bool(!b1);
    { !b1 } -> Booleanbool;
    requires Same<decltype(b1 && b2), bool>;
    {b1 && b2} -> Same<bool>;
    requires Same<decltype(b1 || b2), bool>;
    {b1 || b2} -> Same<bool>;
};
```

- <sup>1</sup> The Boolean concept describes the requirements on a type that is usable in Boolean contexts.
- <sup>2</sup> Given values b1 and b2 of type B, and a value t1 of type bool, then type B models Boolean if and only if
- (2.1) bool(b1) == t1[] (bool x) { return x; }(b1) for every value b1 implicitly converted to t1.
- (2.2) bool(b1) == !bool(!b1) for every value b1.
- (2.3) (b1 && b2) == , (b1 && bool(b2)), and (bool(b1) && b2) are all semantically identical to (bool(b1) && bool(b2)), including short-circuit evaluation.

```
(2.4)
       — (b1 || b2) ==, (b1 || bool(b2)), and (bool(b1) || b2) are all semantically identical to (bool(b1)
           | | bool(b2)), including short-circuit evaluation.
     [Example: The types bool, std::true_type, and std::bitset<>::reference are Boolean types. — end
     example
     19.2.7 Concept Integral
                                                                       [concepts.lib.corelang.integral]
     template <class T>
     concept bool Integral = is_integral<T>::value;
          The Integral concept is used when requiring that a type T is an integral type (3.9.1).
              Concept SignedIntegral
                                                               [concepts.lib.corelang.signedintegral]
     19.2.8
     template <class T>
     concept bool SignedIntegral =
       Integral<T> && is_signed<T>::value;
  1
          The SignedIntegral concept is used when requiring that a type T is an integral type that is signed.
  2
          Note: SignedIntegral<T> may be true even for types that are not signed integral types (3.9.1).
           - end note]
     19.2.9 Concept UnsignedIntegral
                                                            [concepts.lib.corelang.unsignedintegral]
     template <class T>
     concept bool UnsignedIntegral =
       Integral<T> && !SignedIntegral<T>;
  1
          The UnsignedIntegral concept is used when requiring that a type T is an integral type that is
          unsigned.
  2
          Note: UnsignedIntegral<T> may be true even for types that are not unsigned integral types (3.9.1).
           - end note]
     19.2.10 Concept DefaultConstructible
                                                        [concepts.lib.corelang.defaultconstructible]
     [Editor's note: Remove table [defaultconstructible] in [utility.arg.requirements]. Replace references to [de-
     faultconstructible] with references to [concepts.lib.corelang.defaultconstructible].]
     template <class T>
     concept bool DefaultConstructible =
       is_default_constructible<T>::value;
       requires {
          T{};
       };
          [Editor's note: REVIEW: The C++14 DefaultConstructible requirements table also requires T() as
          a valid expression, but that disallows array types. However, is default constructible<int[4]>::value
          is true. It's not clear to me whether the requirements table is wrong or whether the exclusion of array
          types was intentional. Also, the text below seems to duplicate the normative wording above, so I
          propose to strike it.]
          A type T models DefaultConstructible if and only if
(1.1)
            — The definition T u{}; value-initializes (8.5) object u.
(1.2)
            — The definition T t; default-initializes (8.5) object t.
(1.3)
               The expressions T() and T{} value-initialize (8.5) temporary objects of type T.
```

§ 19.2.10 7

#### 19.2.11 Concept MoveConstructible [concepts.lib.corelang.moveconstructible]

[Editor's note: Remove table [moveconstructible] in [utility.arg.requirements]. Replace references to [moveconstructible] with references to [concepts.lib.corelang.moveconstructible].]

```
template <class T>
concept bool MoveConstructible =
    is_move_constructible<T>::value;
    requires (T t) {
        T(move(t));
    };
```

1

- Let rv be an rvalue of type T. Then a type T models MoveConstructible if and only if
- (1.1) After the definition T u = rv;, u is equal to the value of rv before the construction.
- (1.2) T(rv) is equal to the value of rv before the construction.
  - rv's state is unspecified. [Note: rv must still meet the requirements of the library component that is using it. The operations listed in those requirements must work as specified whether rv has been moved from or not.—end note]

#### 19.2.12 Concept CopyConstructible [concepts.lib.corelang.copyconstructible]

[Editor's note: Remove table [copyconstructible] in [utility.arg.requirements]. Replace references to [copyconstructible] with references to [concepts.lib.corelang.copyconstructible].]

```
template <class T>
concept bool CopyConstructible =
   MoveConstructible<T> && is_copy_constructible<T>::value;
   requires (T a, const T& b) {
        T(a);
        T(b);
        T((const T&&)b);
   };
```

- Let v be an lvalue of type (possibly const) T or an rvalue of type const T. Then a type T models CopyConstructible if and only if
- (1.1) After the definition T u = v;, v is unchanged and is equal to u.
- (1.2) T(v) is equal to v and v is unchanged.

#### 19.2.13 Concept Constructible

[concepts.lib.corelang.constructible]

```
template <class T, class ...Args>
concept bool Constructible =
   is_constructible<T, Args...>::value;
   requires ( Args...args ) {
       T{forward<Args>(args)...};
   };
```

The Constructible concept is used when requiring that a type T is constructible with arguments of types Args....

#### 19.2.14 Concept Destructible

[concepts.lib.corelang.destructible]

[Editor's note: Remove table [destructible] in [utility.arg.requirements]. Replace references to [destructible] with references to [concepts.lib.corelang.destructible].]

```
template <class T>
concept bool Destructible =
```

1

1

[Editor's note: REVIEW: The expression  $t.\sim T()$  comes straight from the requirements table for the Destructible concept in C++14. However,  $t.\sim T()$  is not valid if T is a reference or array type. We need to decide whether we want Destructible<int&> and Destructible<int[42]> to be true or false.]

A type T models Destructible if and only if

— After the expression u.~T(), all resources owned by u are reclaimed and no exception is propagated.

#### 19.2.15 Concept MoveAssignable

#### [concepts.lib.corelang.moveassignable]

[Editor's note: Remove table [moveassignable] in [utility.arg.requirements]. Replace references to [moveassignable] with references to [concepts.lib.corelang.moveassignable].]

```
template <class T>
concept bool MoveAssignable =
    is_move_assignable<T>::value;
    requires(T a, T b) {
      { a = move(b) } -> Same<T&>;
      };
```

Let rv be an rvalue of type T <u>and let t be an lvalue of type T</u>. Then a-type T models MoveAssignable if and only if

- (addressof(t = rv) == addressof(t)) != false).
- (1.2) The expression t = rv is an lvalue of type (non-const) T, the expression returns a reference to t, and aAfter the assignment t is equal to the value of rv before the assignment.
  - rv's state is unspecified. [Note: rv must still meet the requirements of the library component that is using it. The operations listed in those requirements must work as specified whether rv has been moved from or not. —end note]

#### 19.2.16 Concept CopyAssignable

#### [concepts.lib.corelang.copyassignable]

[Editor's note: Remove table [copyassignable] in [utility.arg.requirements]. Replace references to [copyassignable] with references to [concepts.lib.corelang.copyassignable].]

```
template <class T>
concept bool CopyAssignable =
  MoveAssignable<T> && is_copy_assignable<T>::value;
  requires(T a, T b, const T& c) {
    { a = b } -> Same<T&>;
    { a = c } -> Same<T&>;
    { a = (const T&&) c } -> Same<T&>;
  };
```

Let <u>t</u> be an lvalue of type <u>T</u>, and <u>v</u> be an lvalue of type (possibly const) <u>T</u> or an rvalue of type const <u>T</u>. Then a-type <u>T</u> models <u>CopyAssignable</u> if and only if

- (addressof(t = v) == addressof(t)) != false).
- (1.2) The expression t = v is an lvalue of type (non-const) T, the expression returns a reference to t, v is unchanged, and a After the assignment t is equal to v and v is unchanged.

#### 19.2.17 Concept Assignable

[concepts.lib.corelang.assignable]

```
template <class T, class U = T>
concept bool Assignable =
  requires(T a, U b) {
    { a = forward<U>(b) } -> Same<T&>;
};
```

Let t be an lvalue of type T. If U is a reference type, let v be a lvalue of type U; otherwise, let v be an rvalue of type U. Then types T and U model Assignable if and only if

- (addressof(t = v) == addressof(t)) != false).

#### 19.2.18 Concept Swappable

1

2

#### [concepts.lib.corelang.swappable]

[Editor's note: Remove subclause [swappable.requirements]. Replace references to [swappable.requirements] with [concepts.lib.corelang.swappable].]

```
template <class T>
concept bool Swappable() {
  return requires(T t, T u) {
    swap(forward<T>(t), forward<T>(u));
  <u>};</u>
}
template <class T, class U = T>
concept bool Swappable() { =
  return Swappable<T>() &&
    Swappable<U>() &&
    Common<T, U> &&
    requires(T t, U u) {
      swap(forward<T>(t), forward<U>(u));
      swap(forward<U>(u), forward<T>(t));
    };
}
```

[Editor's note: The following is copied almost verbatim from [swappable.requirements]]

- This subclause provides definitions for swappable types and expressions. In these definitions, let t denote an expression of type T, and let u denote an expression of type U.
  - An object t is *swappable with* an object u if and only if types T and U model Swappable. Types T and U model Swappable if and only if:
- (2.1) the requires clause above is evaluated in the context described below, and
- (2.2) these expressions have the following effects:
- (2.2.1) the object referred to by t has the value originally held by u and
- the object referred to by u has the value originally held by t.
  - The context in which the requires clause is evaluated shall ensure that a binary non-member function named "swap" is selected via overload resolution (13.3) on a candidate set that includes:
- (3.1) the two swap function templates defined in <utility> (20.2) and
- (3.2) the lookup set produced by argument-dependent lookup (3.4.2).

[Note: If T and U are both fundamental types or arrays of fundamental types and the declarations from the header <utility> are in scope, the overall lookup set described above is equivalent to that of the qualified name lookup applied to the expression std::swap(t, u) or std::swap(u, t) as appropriate. — end note

[Note: It is unspecified whether a library component that has a swappable requirement includes the header  $\langle \mathtt{utility} \rangle$  to ensure an appropriate evaluation context.  $-end\ note$ ]

An rvalue or lvalue t is *swappable* if and only if t is swappable with any rvalue or lvalue, respectively, of type T.

[Example: User code can ensure that the evaluation of swap calls is performed in an appropriate context under the various conditions as follows:

```
#include <utility>
 // Requires: std::forward<T>(t) shall be swappable with std::forward<U>(u).
 template <class T, class U>
 void value_swap(T&& t, U&& u) {
   using std::swap;
   swap(std::forward<T>(t), std::forward<U>(u)); // OK: uses "swappable with" conditions
                                                    // for rvalues and lvalues
 }
 // Requires: lvalues of T shall be swappable.
 template <class T>
 void lv_swap(T& t1, T& t2) {
   using std::swap;
   swap(t1, t2);
                                                    // OK: uses swappable conditions for
                                                    // lvalues of type T
 namespace N {
   struct A { int m; };
   struct Proxy { A* a; };
   Proxy proxy(A& a) { return Proxy{ &a }; }
   void swap(A& x, Proxy p) {
                                                    // OK: uses context equivalent to swappable
     std::swap(x.m, p.a->m);
                                                    // conditions for fundamental types
   void swap(Proxy p, A& x) { swap(x, p); }
                                                    // satisfy symmetry constraint
 int main() {
   int i = 1, j = 2;
   lv_swap(i, j);
   assert(i == 2 && j == 1);
   N::A a1 = { 5 }, a2 = { -5 };
   value_swap(a1, proxy(a2));
   assert(a1.m == -5 \&\& a2.m == 5);
— end example]
```

#### 19.3 Foundational concepts

[concepts.lib.foundational]

#### 19.3.1 In general

[concepts.lib.foundational.general]

<sup>1</sup> This section describes the foundational concepts that describe the basis of the value-oriented programming style on which the library is based. The purpose of these concepts is to establish a foundation for equational reasoning in programs.

§ 19.3.1

#### 19.3.2 Concept EqualityComparable [concepts.lib.foundational.equalitycomparable]

[Editor's note: Remove table [equalitycomparable] in [utility.arg.requirements]. Replace references to [equalitycomparable] with [concepts.lib.equalitycomparable].]

```
template <class T>
     concept bool EqualityComparable() {
       return requires(T a, T b) {
         {a == b} -> Boolean;
         {a != b} -> Boolean;
       };
     }
          Let a, b, and c be well-formed objects of type T. Then type T models EqualityComparable if and only
(1.1)
            — (a == a) != false.
(1.2)
            — (a == b) != false if and only if a is equal to b.
            — (a == b) != false if and only if (b == a) != false.
(1.3)
            — (a != b) != false if and only if (a == b) == false.
(1.4)
(1.5)
            — (a == b) != false && (b == c) != false if and only if (a == c) != false.
  2
           [Note: Not all arguments will be well-formed for a given type. For example, NaN is not a well-formed
          floating point value, and many types' moved-from states are not well-formed. This does not mean that
          the type does not model EqualityComparable. — end note]
     template <class T, class U>
     concept bool EqualityComparable() {
       return Common<T, U> &&
         EqualityComparable<T>() &&
         EqualityComparable<U>() &&
         EqualityComparable<CommonType<T, U>>() &&
         requires(T a, U b) {
           {a == b} -> Boolean;
           {b == a} -> Boolean;
           {a != b} -> Boolean;
           {b != a} -> Boolean;
         };
     }
  3
          Let a be an object of type T, b be an object of type U, and C be CommonType<T, U>. Then types T and
          U model EqualityComparable if and only if
(3.1)
            — (a == b) != false if and only if (C_{\{a\}}) == C_{\{b\}}) != false.
(3.2)
            — (a != b) != false if and only if (C\{(a\})) != C\{(b\})) != false.
(3.3)
            — (b == a) != false if and only if (C\{(b\})) == C\{(a\})) != false.
(3.4)
            — (b != a) != false if and only if (C_{\{b\}}) != C_{\{a\}}) != false.
```

[Editor's note: BUGBUG There is concern on the committee that the Common requirement is overconstraining here. (In Relation too.]

#### 19.3.3 Concept Semiregular

[concepts.lib.foundational.semiregular]

```
template <class T>
concept bool Semiregular =
  DefaultConstructible<T> &&
```

§ 19.3.3

```
CopyConstructible<T> &&
       Destructible<T> &&
       CopyAssignable<T> &&
       requires(T a, size_t n) {
         // Object
         requires Same<T*, decltype(&a)>;
         {&a} -> Same<T*>;
          // Destruction
         { a.~T() } noexcept;
          // Allocation
         requires Same<T*, decltype(new T)>;
         requires Same<T*, decltype(new T[n])>;
          \{\text{new T}\} \rightarrow \text{Same} < T*>;
          {new T[n]} \rightarrow Same < T*>;
          // Deallocation
         \{ delete new T \rightarrow \};
         \{-delete new T[n]-\};
       };
     Editor's note: The concepts are probably too fine-grained here. Look again at "The Palo Alto" report; in
     particular, at the definition of Semiregular in Appendix D.]
           Let a be any well-formed object of type T. Then type T models Semiregular if and only if
(1.1)
             — (&a == addressof(a)) != false.
(1.2)
                a is not a volatile object or const volatile object (3.9.3).
           Note: The Semiregular concept is modeled by types that have behave similarly to built-in types like
           int, except that they may not be comparable with ==. — end note]
     19.3.4 Concept Regular
                                                                     [concepts.lib.foundational.regular]
     template <class T>
     concept bool Regular =
       Semiregular<T>() && EqualityComparable<T>;
           Note: The Regular concept is modeled by types that behave similarly to built-in types like int and
           that are comparable with ==. — end note
               Concept TotallyOrdered
                                                            [concepts.lib.foundational.totallyordered]
     [Editor's note: Remove table [lessthancomparable] in [utility.arg.requirements]. Replace uses of LessThanComparable
     with TotallyOrdered (acknowledging that this is a breaking change that makes type requirements stricter).
     Replace references to [lessthancomparable] with references to [concepts.lib.totallyordered]]
     template <class T>
     concept bool TotallyOrdered() {
       return EqualityComparable<T>() &&
         requires (T a, T b) {
           { a < b } -> Boolean;
           { a > b } -> Boolean;
           { a <= b } -> Boolean;
            { a >= b } -> Boolean;
         };
     }
  1
           Let a, b, and c be well-formed objects of type T. Then type T models TotallyOrdered if and only if
            - (a < a) == false.
(1.1)
(1.2)
            — If (a < b) != false, then (b < a) == false.
```

§ 19.3.5

```
(1.3)
            — If (a < b) != false and (b < c) != false, then (a < c) != false.
(1.4)
            — Exactly one of the following is true: (a < b) != false, or (b < a) != false, or (a == b) !=
                false.
(1.5)
            — (a > b) != false if and only if (b < a) != false.
(1.6)
            — (a \le b) != false if and only if <math>(b \le a) == false.
(1.7)
            — (a \ge b) != false if and only if <math>(b \ge a) == false.
  2
           Note: Not all arguments will be well-formed for a given type. For example, NaN is not a well-formed
           floating point value, and many types' moved-from states are not well-formed. This does not mean that
           the type does not model TotallyOrdered. — end note
     template <class T, class U>
     concept bool TotallyOrdered() {
       return Common<T, U> &&
         TotallyOrdered<T>() &&
         TotallyOrdered<U>() &&
         TotallyOrdered<CommonType<T, U>>() &&
         EqualityComparable<T, U>() &&
         requires (T a, U b) {
           { a < b } -> Boolean;
           { a > b } -> Boolean;
           { a <= b } -> Boolean;
           { a >= b } -> Boolean;
           { b < a } -> Boolean;
           { b > a } -> Boolean;
           { b <= a } -> Boolean;
           { b >= a } -> Boolean;
         }:
     }
  3
           Let a be an object of type T, b be an object of type U, and C be CommonType<T, U>. Then types T
           and U model EqualityComparable if and only if
(3.1)
            — (a < b) != false if and only if (C\{(a\}) < C\{(b\})) != false.
(3.2)
            — (a > b) != false if and only if (C\{(a\}) > C\{(b\})) != false.
(3.3)
            — (a \leq b) != false if and only if (C(\{a\}) \leq C(\{b\})) != false.
(3.4)
            — (a >= b) != false if and only if (C\{(a\}) >= C\{(b\})) != false.
(3.5)
            — (b < a) != false if and only if (C_{(b)} < C_{(a)}) != false.
(3.6)
            — (b > a) != false if and only if (C\{(b\})) > C\{(a\}) != false.
(3.7)
            — (b <= a) != false if and only if (C\{(b\}) \le C\{(a\})) != false.
(3.8)
            — (b >= a) != false if and only if (C\{(b\}) >= C\{(a\})) != false.
```

#### 19.4 Function concepts

[concepts.lib.functions]

#### 19.4.1 In general

[concepts.lib.functions.general]

<sup>1</sup> The function concepts in this section describe the requirements on function objects (20.9) and their arguments.

§ 19.4.1

[concepts.lib.functions.function]

19.4.2 Concept Function

```
template <class F, class...Args>
     using ResultType = result_of_t<F(Args...)>;
     template <class F, class...Args>
     concept bool Function =
       Destructible<T> &&
       CopyConstructible<T> &&
       requires (F f, Args...args) {
         typename ResultType<F, Args...>;
         requires Same<F*, decltype(&f)>;
         { &f } -> Same<F*>;
         { f.~F() } noexcept;
         requires Same<F*, decltype(new F)>;
         { new F } -> Same<F*>;
         \{ delete new F \rightarrow \};
         { f(forward<Args>(args)...) };
         requires Same<ResultType<F, Args...>,
                       decltype(f(forward<Args>(args)...))>;
         { f(forward<Args>(args)...) } -> Same<ResultType<F, Args...> >;
  1
          Let f be any object of type F. Then types F and Args... model Function if and only if
(1.1)
            — (&f == addressof(f)) != false.
          The function call expression need not be equality-preserving; that is, the expression f(args...) is
          allowed to return non-equal objects when called with equal arguments, and still model Function.
  3
          Note: Since models of Function are allowed to be non-equality-preserving, a function that generates
          random numbers may model Function. — end note]
              Concept RegularFunction
                                                            [concepts.lib.functions.regularfunction]
     template <class F, class...Args>
     concept bool RegularFunction =
       Function<F, Args...>;
  1
          Models of RegularFunction shall be equality-preserving; that is, when passed equal arguments, they
          shall return equal objects.
  2
          [Note: A random number generator is not a model of RegularFunction. — end note]
  3
          [Note: There is no syntactic difference between Function and RegularFunction. — end note]
     19.4.4 Concept Predicate
                                                                   [concepts.lib.functions.predicate]
     template <class F, class...Args>
     concept bool Predicate =
       RegularFunction<F, Args...> &&
       Convertible<ResultType<F, Args...>, bool>;
                                                                     [concepts.lib.functions.relation]
     19.4.5 Concept Relation
     template <class F, class T>
     concept bool Relation() {
       return Predicate<F, T, T>;
     template <class R, class T, class U>
     § 19.4.5
                                                                                                       15
```

```
concept bool Relation() {
        return Relation<R. T>() &&
          Relation<R, U>() &&
          Common<T, U> &&
          Relation<R, CommonType<T, U>>() &&
          requires (R r, T a, U b) {
            \{ r(a, b) \} \rightarrow Boolean;
            { r(b, a) } -> Boolean;
          };
      }
    1
            Let r be any well-formed object of type R, a be any well-formed object of type T, b be any well-formed
            object of type U, and C be CommonType<T, U>. Then types R, T, and U model Relation if and only if
 (1.1)
              — r(a, b) = false if and only if <math>r(C(a)), C(b)) = false.
             - r(b, a) != false if and only if r(C(\{b\}), C(\{a\})) != false.
 (1.2)
      19.4.6 Concept StrictWeakOrder
                                                               [concepts.lib.functions.strictweakorder]
      template <class F, class T>
      concept bool StrictWeakOrder() {
        return Relation<F, T>();
      template <class R, class T, class U>
      concept bool StrictWeakOrder() {
        return Relation<R, T, U>();
      }
            Let comp be a well-formed object of type Comp. Then type Comp models concept StrictWeakOrder if
            and only if it imposes a strict weak ordering on its arguments.
            [Editor's note: Copied verbatim from [alg.sorting].]
    2
            The term strict refers to the requirement of an irreflexive relation (!comp(x, x) for all x), and the
            term weak to requirements that are not as strong as those for a total ordering, but stronger than
            those for a partial ordering. If we define equiv(a, b) as !comp(a, b) && !comp(b, a), then the
            requirements are that comp and equiv both be transitive relations:
 (2.1)
              - comp(a, b) && comp(b, c) implies comp(a, c)
 (2.2)
             — equiv(a, b) && equiv(b, c) implies equiv(a, c) [Note: Under these conditions, it can be
                 shown that
(2.2.1)
                  — equiv is an equivalence relation
(2.2.2)
                  — comp induces a well-defined relation on the equivalence classes determined by equiv
(2.2.3)
                  — The induced relation is a strict total ordering. — end note
```

§ 19.4.6

## 20 General utilities library

Utility components

1

3

5

## [utilities]

[utility]

```
[Editor's note: Change the <utility> synopsis as follows:]
    // 20.2.2, swap:
    template<class T>
      requires MoveConstructible<T> && MoveAssignable<T>
   void swap(T& a, T& b) noexcept(see below);
    template <class T, size_t N>
      requires requires (std::remove_all_extents_t<T>& t) { swap(t, t); }
    void swap(T (&a)[N], T (&b)[N]) noexcept(noexcept(swap(*a, *b)));}
    // 20.2.3, exchange:
    template <class T, class U=T>
      requires MoveConstructible<T> && Assignable<T, U>
   T exchange(T& obj, U&& new_val);
20.2.2
                                                                                      [utility.swap]
         swap
template<class T>
 requires MoveConstructible<T> && MoveAssignable<T>
void swap(T& a, T& b) noexcept(see below);
     Remark: The expression inside noexcept is equivalent to:
       is_nothrow_move_constructible<T>::value &&
       is_nothrow_move_assignable<T>::value
     -Requires: Type T shall be MoveConstructible (Table ??) and MoveAssignable (Table ??).
     Effects: Exchanges values stored in two locations.
template <class T, size_t N>
    requires requires (std::remove_all_extents_t<T>& t) { swap(t, t); }
void swap(T (&a)[N], T (&b)[N]) noexcept(noexcept(swap(*a, *b)));}
     -Requires: a[i] shall be swappable with (??) b[i] for all i in the range [0,N).
     Effects: swap_ranges(a, a + N, b)
                                                                                 [utility.exchange]
20.2.3
        exchange
template <class T, class U=T>
 requires MoveConstructible<T> && Assignable<T, U>
T exchange(T& obj, U&& new_val);
     Effects: Equivalent to:
       T old_val = std::move(obj);
       obj = std::forward<U>(new_val);
       return old_val;
```

§ 20.2.3

#### 20.9 Function objects

[function.objects]

[Editor's note: To <functional> header synopsis, add identity function object.]

Header <functional> synopsis

```
struct identity;
```

[Editor's note: Add constraints to the comparison function objects.]

#### 20.9.6 Comparisons

1

[comparisons]

The library provides basic function object classes for all of the comparison operators in the language (5.9, 5.10).

```
template <class T = void>
          requires EqualityComparable<T>() || Same<T, void>
        struct equal_to {
          constexpr bool operator()(const T& x, const T& y) const;
          typedef T first_argument_type;
          typedef T second_argument_type;
          typedef bool result_type;
        };
2
             operator() returns x == y.
        template \langle class\ T = void \rangle
          requires EqualityComparable<T>() || Same<T, void>
        struct not_equal_to {
          constexpr bool operator()(const T& x, const T& y) const;
          typedef T first_argument_type;
          typedef T second_argument_type;
          typedef bool result_type;
        };
3
             operator() returns x != y.
        template \langle class\ T = void \rangle
          requires TotallyOrdered<T>() || Same<T, void>
        struct greater {
          constexpr bool operator()(const T& x, const T& y) const;
          typedef T first_argument_type;
          typedef T second_argument_type;
          typedef bool result_type;
        };
             operator() returns x > y.
        template <class T = void>
          requires TotallyOrdered<T>() || Same<T, void>
        struct less {
          constexpr bool operator()(const T& x, const T& y) const;
          typedef T first_argument_type;
          typedef T second_argument_type;
          typedef bool result_type;
        };
5
             operator() returns x < y.
        template <class T = void>
          requires TotallyOrdered<T>() || Same<T, void>
        struct greater_equal {
```

§ 20.9.6

```
constexpr bool operator()(const T& x, const T& y) const;
          typedef T first_argument_type;
          typedef T second_argument_type;
          typedef bool result_type;
        };
6
             operator() returns x \ge y.
        template <class T = void>
          requires TotallyOrdered<T>() || Same<T, void>
        struct less_equal {
          constexpr bool operator()(const T& x, const T& y) const;
          typedef T first_argument_type;
          typedef T second_argument_type;
          typedef bool result_type;
        };
7
             operator() returns x <= y.
        template <> struct equal_to<void> {
          template <class T, class U>
            requires EqualityComparable<T, U>()
          constexpr boolauto operator()(T&& t, U&& u) const
            -> decltype(std::forward<T>(t) == std::forward<U>(u));
          typedef unspecified is_transparent;
8
             operator() returns std::forward<T>(t) == std::forward<U>(u).
        template <> struct not_equal_to<void> {
          template <class T, class U>
            requires EqualityComparable<T, U>()
          constexpr boolauto operator()(T&& t, U&& u) const
            -> decltype(std::forward<T>(t) != std::forward<U>(u));
          typedef unspecified is_transparent;
        };
9
             operator() returns std::forward<T>(t) != std::forward<U>(u).
        template <> struct greater<void> {
          template <class T, class U>
            requires TotallyOrdered<T, U>()
          constexpr boolauto operator()(T&& t, U&& u) const
            -> decltype(std::forward<T>(t) > std::forward<U>(u));
          typedef unspecified is_transparent;
        };
10
             operator() returns std::forward<T>(t) > std::forward<U>(u).
        template <> struct less<void> {
          template <class T, class U>
            requires TotallyOrdered<T, U>()
          constexpr boolauto operator()(T&& t, U&& u) const
            -> decltype(std::forward<T>(t) < std::forward<U>(u));
          typedef unspecified is_transparent;
        };
11
             operator() returns std::forward<T>(t) < std::forward<U>(u).
```

§ 20.9.6

```
template <> struct greater_equal<void> {
           template <class T, class U>
            requires TotallyOrdered<T, U>()
           constexpr boolauto operator()(T&& t, U&& u) const
            -> decltype(std::forward<T>(t) >= std::forward<U>(u));
           typedef unspecified is_transparent;
        };
12
             operator() returns std::forward<T>(t) >= std::forward<U>(u).
        template <> struct less_equal<void> {
           template <class T, class U>
            requires TotallyOrdered<T, U>()
           constexpr boolauto operator()(T&& t, U&& u) const
            -> decltype(std::forward<T>(t) <= std::forward<U>(u));
           typedef unspecified is_transparent;
        };
13
             operator() returns std::forward<T>(t) <= std::forward<U>(u).
14
        For templates greater, less, greater_equal, and less_equal, the specializations for any
        pointer type yield a total order, even if the built-in operators <, >, <=, >= do not.
   [Editor's note: After subsection 20.9.12 [unord.hash] add the following subsection:]
   20.9.13 Class identity
                                                                                        [func.identity]
   struct identity {
     template <class T>
     constexpr T&& operator()(T&& t) const noexcept;
   };
 1
        operator() returns std::forward<T>(t).
        [Editor's note: REVIEW: From Stephan T. Lavavej: "[This] identity functor, being a non-template,
        clashes with any attempt to provide identity<T>::type." <Insert bikeshed naming discussion here>.]
```

§ 20.9.13

### 24 Iterators library

## [iterators]

24.1 General [iterators.general]

<sup>1</sup> This Clause describes components that C++ programs may use to perform iterations over containers (Clause 23), streams (27.7), and stream buffers (27.6), and ranges (24.10.2.4).

<sup>2</sup> The following subclauses describe iterator requirements, and components for iterator primitives, predefined iterators, and stream iterators, as summarized in Table 2.

	Subclause	Header(s)
24.2	Requirements	
24.7	Iterator primitives	<iterator></iterator>
24.8	Predefined iterators	
24.9	Stream iterators	
24.10	<u>Iterables</u> Ranges	

#### 24.2 Iterator requirements

#### [iterator.requirements]

#### 24.2.1 In general

#### [iterator.requirements.general]

- Iterators are a generalization of pointers that allow a C++ program to work with different data structures (for example, containers and ranges) in a uniform manner. To be able to construct template algorithms that work correctly and efficiently on different types of data structures, the library formalizes not just the interfaces but also the semantics and complexity assumptions of iterators. All input iterators i support the expression \*i, resulting in a value of some object type T, called the value type of the iterator. All output iterators support the expression \*i = o where o is a value of some type that is in the set of types that are writable to the particular iterator type of i. All iterators i for which the expression (\*i) .m is well-defined, support the expression i->m with the same semantics as (\*i) .m. For every iterator type X for which equality is defined, there is a corresponding signed integer type called the difference type of the iterator.
- <sup>2</sup> Since iterators are an abstraction of pointers, their semantics is a generalization of most of the semantics of pointers in C++. This ensures that every function template that takes iterators works as well with regular pointers. This International Standard defines fiveseven categories of iterators, according to the operations defined on them: weak input iterators, input iterators, weak output iterators, output iterators, forward iterators, bidirectional iterators and random access iterators, as shown in Table 3.

Table 3 — Relations among iterator categories

Random Access	ightarrow Bidirectional	ightarrow Forward	ightarrow Input	$ ightarrow \mathbf{WeakInput}$
			ightarrow Output	$ ightarrow \mathbf{WeakOutput}$

- The seven categories of iterators correspond to the iterator concepts WeakInputIterator, InputIterator, WeakOutputIterator, OutputIterator, ForwardIterator, BidirectionalIterator, and RandomAccess-Iterator, respectively. The generic term iterator refers to any type that models WeakIterator.
- <sup>4</sup> Forward Input iterators satisfy all the requirements of weak input iterators and can be used whenever ana weak input iterator is specified; Forward iterators also satisfy all the requirements of input iterators and can be used whenever an input iterator is specified; Bidirectional iterators also satisfy all the requirements

of forward iterators and can be used whenever a forward iterator is specified; Random access iterators also satisfy all the requirements of bidirectional iterators and can be used whenever a bidirectional iterator is specified.

- <sup>5</sup> Iterators that further satisfy the requirements of <u>weak</u> output iterators are called *mutable iterators*. Non-mutable iterators are referred to as *constant iterators*.
- Just as a regular pointer to an array guarantees that there is a pointer value pointing past the last element of the array, so for any iterator type there is an iterator value that points past the last element of a corresponding sequence. These values are called past-the-end values. Values of an iterator i for which the expression \*i is defined are called dereferenceable. The library never assumes that past-the-end values are dereferenceable. Iterators can also have singular values that are not associated with any sequence. [Example: After the declaration of an uninitialized pointer x (as with int\* x;), x must always be assumed to have a singular value of a pointer. —end example] Results of most expressions are undefined for singular values; the only exceptions are destroying an iterator that holds a singular value, the assignment of a non-singular value to an iterator that holds a singular value, and, for iterators that satisfy the DefaultConstructible requirements, using a value-initialized iterator as the source of a copy or move operation. [Note: This guarantee is not offered for default initialization, although the distinction only matters for types with trivial default constructors such as pointers or aggregates holding pointers. —end note] In these cases the singular value is overwritten the same way as any other value. Dereferenceable values are always non-singular.
- <sup>7</sup> A sentinel is an abstraction of a past-the-end iterator. Sentinels are Regular types that can be used to denote the end of a range. A sentinel and an iterator denoting a range shall be EqualityComparable. A sentinel denotes an element when an iterator i compares equal to the sentinel, and i points to that element.
- <sup>8</sup> An iterator or sentinel j is called *reachable* from an iterator i if and only if there is a finite sequence of applications of the expression ++i that makes i == j. If j is reachable from i, they refer to elements of the same sequence.
- Most of the library's algorithmic templates that operate on data structures have interfaces that use ranges. A range is a pair of iterators or an iterator and a sentinel that designate the beginning and end of the computation. A range [i,i) is an empty range; in general, a range [i,j) refers to the elements in the data structure starting with the element pointed to by i and up to but not including the element pointed todenoted by j. Range [i,j) is valid if and only if j is reachable from i. The result of the application of functions in the library to invalid ranges is undefined.
- All the categories of iterators require only those functions that are realizable for a given category in constant time (amortized). Therefore, requirement tables for the iterators do not have a complexity column.
- 11 Destruction of an iterator may invalidate pointers and references previously obtained from that iterator.
- 12 An *invalid* iterator is an iterator that may be singular. <sup>1</sup>
- In the following sections, a and b denote values of type X or const X, difference\_type and reference refer to the types <a href="iterator\_traits<X>::difference\_typeDifferenceType<X">iterator\_traits<X>::reference ReferenceType<X</a>, respectively, n denotes a value of difference\_type, u, tmp, and m denote identifiers, r denotes a value of X&, t denotes a value of value type T, o denotes a value of some type that is writable to the <a href="weak">weak</a> output iterator. [Note: For an iterator type X there must be an instantiation of <a href="iterator\_traits<X>(24.4.1)the type aliases DifferenceType<X> and ReferenceType<X> must be well-formed. end note]</a>

#### 24.2.2 Concept Readable

[readable.iterators]

<sup>1</sup> The Readable concept is modeled by types that are readable by applying operator\* including pointers, smart pointers, and iterators.

<sup>1)</sup> This definition applies to pointers, since pointers are iterators. The effect of dereferencing an iterator that has been invalidated is undefined.

```
template <class I>
concept bool Readable =
  Semiregular<I> &&
  requires (I i) {
    typename ValueType<I>;
    { *i } -> const ValueType<I>&; // pre: i is dereferenceable
};
```

<sup>2</sup> A Readable type has an associated value type that can be accessed with the ValueType alias template.

```
template <class, class = void> struct value_type { };
template <class T>
struct value_type<T*>
  : enable_if<<del>!is_void</del>is_object<T>::value, remove_cv_t<T>> { };
template <class T>
struct value_type<T[]> : remove_cv<T> { };
template <class T, size_t N>
struct value_type<T[N]> : remove_cv<T> { };
template <class I>
struct value_type<I const> : value_type<decay_t<I>>> { };
template <class I>
struct value_type<I volatile> : value_type<decay_t<I>>> { };
template <class I>
struct value_type<I const volatile> : value_type<decay_t<I>>> { };
template <class T>
  requires requires { typename T::value_type; }
struct value_type<T, void_t<typename T::value_type>>
  : enable_if<<del>!is_void</del>is_object<typename T::value_type>::value, typename T::value_type> { };
template <class T>
 requires requires { typename T::element_type; }
struct value_type<T, void_t<typename T::element_type>>
  : enable_if<<del>!is_voidis</del>_object<typename T::element_type>::value, typename T::element_type> { };
template <class T>
  using ValueType = typename value_type<T>::type;
```

- <sup>3</sup> If a type I has an associated value type, then value\_type<I>::type shall name the value type. Otherwise, there shall be no nested type type.
- <sup>4</sup> The value\_type class template may be specialized on user-defined types.
- When instantiated with a type I that has a nested type value\_type, value\_type<I>::type names that type, unless it is void in which case value\_type<I> shall have no nested type type. [Note: Some legacy output iterators define a nested type named value\_type that is an alias for void. These types are not Readable and have no associated value types. end note]
- When instantiated with a type I that has a nested type element\_type, value\_type<I>::type names that type, unless it is void in which case value\_type<I> shall have no nested type type. [Note: Smart pointers like shared\_ptr<int> are Readable and have an associated value type. But a smart pointer like shared\_ptr<void> is not Readable and has no associated value type. end note]

#### 24.2.3 Concept MoveWritable

[movewritable.iterators]

<sup>1</sup> The MoveWritable concept describes the requirements for moving a value into an iterator's referenced object.

```
template <class Out, class T>
concept bool MoveWritable =
   Semiregular<Out> &&
```

<sup>2</sup> Let v be an rvalue or a lvalue of type (possibly const) T, and let o be an dereferenceable object of type Out. Then types T and Out model MoveWritable if and only if

- (2.1) If <u>oOut</u> is <u>dereferenceableReadable</u>, then after the assignment \*o = move(v), the value referred to by \*o is equal to the value of v before the assignment.
  - 3 After the expression \*o = move(v), object o is not required to be dereferenceable.
  - <sup>4</sup> v's state is unspecified. [*Note:* v must still meet the requirements of the library component that is using it. The operations listed in those requirements must work as specified whether v has been moved from or not. end note]
  - <sup>5</sup> [Note: The only valid use of an operator\* is on the left side of the assignment statement. Assignment through the same value of the writable type happens only once. end note]

#### 24.2.4 Concept Writable

[writable.iterators]

<sup>1</sup> The Writable concept describes the requirements for copying a value into an iterator's referenced object.

```
template <class Out, class T>
concept bool Writable =
    Semiregular<Out> &&
    MoveWritable<Out, T> &&
    requires (Out o, T v) {
        {-*o = v-};
    };
```

- <sup>2</sup> Let v be an lvalue of type (possibly const) T or an rvalue of type const T, and let o be an dereferenceable object of type Out. Then types T and Out model Writable if and only if
- (2.1) Alf Out is Readable, after the assignment \*o = v, the value referred to by \*o is equal to the value of v and v is unchanged.

#### 24.2.5 Concept IndirectlyMovable

[indirectlymovable.iterators]

<sup>1</sup> The IndirectlyMovable concept describes the move relationship between a Readable type and a MoveWritable type.

```
template <class I, class Out>
concept bool IndirectlyMovable =
  Readable<I> &&
    Semiregular<Out> &&
    MoveWritable<Out, ValueType<I>>;
```

- <sup>2</sup> Let i be an object of type I, and let o be an dereferenceable object of type Out. Then types I and Out model IndirectlyMovable if and only if
- (2.1) AIf Out is Readable, after the assignment \*o = move(\*i), the value referred to by \*o is equal to the value of \*i before the assignment.

#### 24.2.6 Concept IndirectlyCopyable

[indirectlycopyable.iterators]

<sup>1</sup> The IndirectlyCopyable concept describes the copy relationship between a Readable type and a Writable type.

```
template <class I, class Out>
concept bool IndirectlyCopyable =
   Readable<Out> &&
   Semiregular<Out> &&
   IndirectlyMovable<I, Out> &&
   Writable<Out, ValueType<I>>;
```

<sup>2</sup> Let i be an object of type I, and let o be an <u>dereferenceable</u> object of type Out. Then types I and Out model IndirectlyCopyable if and only if

(2.1) — Alf Out is Readable, after the assignment \*o = \*i, the value referred to by \*o is equal to the value of \*i and the value of \*i is unchanged.

#### 24.2.7 Concept IndirectlySwappable

#### [indirectlyswappable.iterators]

<sup>1</sup> The IndirectlySwappable concept describes a swappable relationship between the value types of two Readable types.

```
template <class I1, class I2 = I1>
concept bool IndirectlySwappable =
  Readable<I1> &&
  Readable<I2> &&
  Swappable<ReferenceType<I1>, ReferenceType<I2>>-&&();
  Swappable<ReferenceType<I1* &&
  Swappable<ReferenceType<I2*;</pre>
```

#### 24.2.8 Concept WeaklyIncrementable

#### [weaklyincrementable.iterators]

The WeaklyIncrementable concept describes types that can be incremented with the pre- and post-increment operators. The increment operations are not required to be equality-preserving, nor is the type required to be EqualityComparable.

```
template <class I>
concept bool WeaklyIncrementable =
  Semiregular<I> &&
  requires (I i) {
    typename DifferenceType<I>;
    requires SignedIntegral<DifferenceType<I>>;
    { ++i };
    requires Same<I&, decltype(++i)>;
    { ++i } -> Same<I&>;
    {-i++-};
};
```

- <sup>1</sup> Not all arguments will be incrementable for a given type. For example *NaN* is not a well-formed floating point value and hence is not incrementable. Likewise, past-the-end iterators are also not incrementable. This does not mean that the type does not model WeaklyIncrementable.
- <sup>2</sup> Let i be an object of type I. Then the type I models WeaklyIncrementable if and only if
- (2.1) If i is incrementable, then ++i moves i to the next element.
- (2.2) If i is incrementable, then (&++i == &i) != false.
- (2.3) If i is incrementable, then i++ moves i to the next element.
- (2.4) ++i is valid if and only if i++ is valid.

[Editor's note: REVIEW Can we be more specific than "moves to the next element"?]

[Editor's note: Copied almost verbatim from the InputIterator description. This wording is removed there.]

Note: For WeaklyIncrementable types, a equals b does <u>not</u> imply that ++a equals ++b. (Equality does not guarantee the substitution property or referential transparency.) Algorithms on weakly incrementable types should never attempt to pass through the same incrementable value twice. They should be single pass algorithms. These algorithms can be used with istreams as the source of the input data through the istream\_iterator class template. — end note]

#### 24.2.9 Concept Incrementable

#### [incrementable.iterators]

The Incrementable concept describes types that can be incremented with the pre- and post-increment operators. The increment operations are required to be equality-preserving, and the type is required to be EqualityComparable.

```
template <class I>
concept bool Incrementable =
  Regular<I> &&
  WeaklyIncrementable<I> &&
   Same<I, decltype(i++)>;
  requires(I i) {
      { i++ } -> Same<I>;
   };
}
```

- 1 Let a and b be incrementable objects of type I. Then the type I models Incrementable if and only if
- (1.1) If (a == b) != false then (++a == ++b) != false.
- (1.2) If (a == b) != false then ((a++, a) == (b++, b)) != false.
- (1.3) If (a == b) != false then (a++ == b) != false.
- (1.4) If (a == b) != false then ((a++, a) == ++b) != false.

[Editor's note: Copied in part from the ForwardIterator description. This wording is removed there.]

<sup>2</sup> [Note: The requirement that a equals b implies ++a equals ++b (which is not true for weakly incrementable types) allows the use of multi-pass one-directional algorithms with types that model Incrementable. — end note]

#### 24.2.10 Concept WeakIterators

#### [weakiterator.iterators]

The <u>WeakIterator requirements concept</u> forms the basis of the iterator concept taxonomy; every iterator satisfies the <u>WeakIterator</u> requirements. This <u>set of requirements concept</u> specifies operations for dereferencing and incrementing an iterator. Most algorithms will require additional operations <u>to compare iterators (24.2.11)</u>, to read (24.2.14) or write (24.2.16) values, or to provide a richer set of iterator movements (24.2.17, 24.2.18, 24.2.19).)

[Editor's note: Remove para 2 and Table 106.]

```
template <class I>
concept bool WeakIterator =
  WeaklyIncrementable<I> &&
  requires(I i) {
    { *i } -> auto&&; // pre: i is dereferenceable
  };
```

§ 24.2.10 26

[ Note: The requirement that the result of dereferencing the iterator is deducable from auto&& effectively means that it cannot be void. —  $end\ note$  ]

#### 24.2.11 Concept Iterator

[iterator.iterators]

<sup>1</sup> The Iterator concept refines WeakIterator (24.2.10) and adds the requirement that the iterator is equality comparable.

<sup>2</sup> In the Iterator concept, the set of values over which == is (required to be) defined can change over time. Each algorithm places additional requirements on the domain of == for the iterator values it uses. These requirements can be inferred from the uses that algorithm makes of == and !=. [Example: the call find(a,b,x) is defined only if the value of a has the property p defined as follows: b has property p and a value i has property p if (\*i==x) or if (\*i!=x and ++i has property p). — end example]

```
template <class I>
concept bool Iterator =
  WeakIterator<I> &&
  EqualityComparable<I>();
```

#### 24.2.12 Concept Sentinel

[sentinel.iterators]

The Sentinel concept defines requirements for a type that is an abstraction of the past-the-end iterator. Its values can be compared to an iterator for equality.

```
template <class T, class I>
concept bool Sentinel =
  Regular<T> &&
  Iterator<I> &&
  EqualityComparable<T, I>();
```

#### 24.2.13 Concept WeakInputIterator

[weakinput.iterators]

The WeakInputIterator concept is a refinement of WeakIterator (24.2.10). It defines requirements for a type whose referred to values can be read (from the requirement for Readable (24.2.2)) and which can be both pre- and post-incremented. However, weak input iterators are not required to be comparable for equality.

```
template <class I>
concept bool WeakInputIterator =
  WeakIterator<I> &&
  Readable<I> &&
  requires(I i) {
    typename IteratorCategory<I>;
    { i++ } -> Readable;
    requires Derived<IteratorCategory<I>, weak_input_iterator_tag>;
};
```

#### 24.2.14 Concept InputIterator

[input.iterators]

[Editor's note: Remove para 1, 2 and Table 107]

<sup>1</sup> The InputIterator concept is a refinement of Iterator (24.2.11) and WeakInputIterator (24.2.13).

```
template <class I>
concept bool InputIterator =
  WeakInputIterator<I> &&
  Iterator<I> &&
  Derived<IteratorCategory<I>, input_iterator_tag>;
```

§ 24.2.14 27

<sup>2</sup> [Note: For input iterators, a == b does not imply ++a == ++b. (Equality does not guarantee the substitution property or referential transparency.) Algorithms on input iterators should never attempt to pass through the same iterator twice. They should be single pass algorithms. Value type T is not required to be a CopyAssignable type (Table 19.2.16). These algorithms can be used with istreams as the source of the input data through the istream\_iterator class template. — end note]

[Editor's note: Section Output iterators renamed to Concept WeakOutputIterator below:]

#### 24.2.15 Concept WeakOutputIterator

[weakoutput.iterators]

[Editor's note: Remove para 1 and Table 108]

The WeakOutputIterator concept is a refinement of WeakIterator (24.2.10). It defines requirements for a type that can be used to write values (from the requirement for Writable (24.2.4)) and which can be both pre- and post-incremented. However, weak output iterators are not required to be comparable for equality.

```
template <class I, class T>
concept bool WeakOutputIterator =
  WeakIterator<I> && Writable<I, T>;
```

2 [Note: The only valid use of an operator\* is on the left side of the assignment statement. Assignment through the same value of the iterator happens only once. Algorithms on output iterators should never attempt to pass through the same iterator twice. They should be single pass algorithms. Equality and inequality might not be defined. Algorithms that take weak output iterators can be used with ostreams as the destination for placing data through the ostream\_iterator class as well as with insert iterators and insert pointers. — end note]

#### 24.2.16 Concept OutputIterator

[output.iterators]

<sup>1</sup> The OutputIterator concept is a refinement of Iterator (24.2.11) and WeakOutputIterator (24.2.15).

```
template <class I, class T>
concept bool OutputIterator =
  WeakOutputIterator<I, T> && Iterator<I>;
```

2 [Note: Output iterators are used by single-pass algoritms that write into a bounded range, like generate. — end note]

#### 24.2.17 Concept ForwardIterator

[forward.iterators]

- <sup>1</sup> A class or pointer type X satisfies the requirements of a forward iterator if
- (1.1) X satisfies the requirements of an input iterator (24.2.14),
- (1.2) X satisfies the DefaultConstructible requirements (17.6.3.1),
- (1.3) if X is a mutable iterator, reference is a reference to T; if X is a const iterator, reference is a reference to const T,
- (1.4) the expressions in Table 109 are valid and have the indicated semantics, and
- (1.5) objects of type X offer the multi-pass guarantee, described below.
  - <sup>2</sup> The ForwardIterator concept refines InputIterator (24.2.14) and adds the multi-pass guarantee, described below.

```
template <class I>
concept bool ForwardIterator =
   InputIterator<I> &&
   Incrementable<I> &&
   Derived<IteratorCategory<I>, forward_iterator_tag>;
```

§ 24.2.17 28

<sup>3</sup> The domain of == for forward iterators is that of iterators over the same underlying sequence. However, value-initialized iterators may be compared and shall compare equal to other value-initialized iterators of the same type. [Note: value initialized iterators behave as if they refer past the end of the same empty sequence — end note]

- <sup>4</sup> Two dereferenceable iterators a and b of type X offer the multi-pass guarantee if:
- (4.1) a == b implies ++a == ++b and
- (4.2) X is a pointer type or the expression (void)++X(a), \*a is equivalent to the expression \*a.
  - <sup>5</sup> [Note: The requirement that a == b implies ++a == ++b (which is not true for input and output iterators) and the removal of the restrictions on the number of the assignments through a mutable iterator (which applies to output iterators) allows the use of multi-pass one-directional algorithms with forward iterators.

     end note]

[Editor's note: Remove Table 109]

- <sup>6</sup> If a and b are equal, then either a and b are both dereferenceable or else neither is dereferenceable.
- <sup>7</sup> If a and b are both dereferenceable, then a == b if and only if \*a and is equal to \*b are bound to the same object.

#### 24.2.18 Concept BidirectionalIterator

[bidirectional.iterators]

- <sup>1</sup> A class or pointer type X satisfies the requirements of a bidirectional iterator if, in addition to satisfying the requirements for forward iterators, the following expressions are valid as shown in Table 110.
- <sup>2</sup> The BidirectionalIterator concept refines ForwardIterator (24.2.17), and adds the ability to move an iterator backward as well as forward.

```
template <class I>
concept bool BidirectionalIterator =
  ForwardIterator<I> &&
  Derived<IteratorCategory<I>, bidirectional_iterator_tag> &&
  requires (I i) {
    {--i };
    requires Same<I&, decltype(--i)>;
    { --i } -> Same<I&>;
    requires Same<I, decltype(i--)>;
    { i-- };
  requires Same<I, decltype(i--)>;
    { i-- } -> Same<I>;
};
```

[Editor's note: Remove table 110]

- <sup>3</sup> A bidirectional iterator r is decrementable only if there exists some s such that ++s == r. The expressions --r and r-- are only valid if r is decrementable.
- <sup>4</sup> Let a and b be decrementable objects of type I. Then I models BidirectionalIterator if and only if:

```
(4.1) — &--a == &a.
```

- (4.2) If (a == b) != false, then (a-- == j) != false.
- (4.3) If (a == b) != false, then ((a--, a) == --j) != false.
- (4.4) If a is incrementable and (a == b) != false, then (--(++a) == b) != false.
- (4.5) If (a == b) != false, then (++(--a) == b) != false.
  - <sup>5</sup> [Note: Bidirectional iterators allow algorithms to move iterators backward as well as forward. end note]

#### 24.2.19 Concept RandomAccessIterator

[random.access.iterators]

<sup>1</sup> A class or pointer type X satisfies the requirements of a random access iterator if, in addition to satisfying the requirements for bidirectional iterators, the following expressions are valid as shown in Table 111.

The RandomAccessIterator concept refines BidirectionalIterator (24.2.18) and adds support for constant-time advancement with +=, +, and -=, and the computation of distance in constant time with -. Random access iterators also support array notation via subscripting.

```
template <class I>
concept bool __MutableIterator = // exposition only
  Iterator<I> &&
  requires(I i) {
      { *i } -> auto&;
      *i = *i;
 };
template <class I>
concept bool RandomAccessIterator =
 BidirectionalIterator<I> &&
 TotallyOrdered<I>() &&
 Derived<IteratorCategory<I>, random_access_iterator_tag> &&
 SizedIteratorRange<I, I> && // see below
 requires (I i, I j, DifferenceType<I> n) {
    {i += n};
    {i+n};
    {n+i};
    {i -= n};
    {i-n};
    requires Same<decltype(i += n), I&>;
   requires Same<decltype(i + n), I>;
   requires Same<decltype(n + i), I>;
   requires Same<decltype(i -= n), I&>;
    requires Same<decltype(i - n), I>;
    { i += n } -> Same < I &>;
    {i + n} \rightarrow Same < I;
    \{n + i\} \rightarrow \overline{Same < I>};
    { i -= n } -> Same < I &>;
    { i - n } -> Same<I>;
    { i[n] } -> const ValueType<I>&;
      _MutableIterator<I> ?
      requires(I i, int n) { i[n] = *i; *i = i[n]; } :
      requires(I i, int n) { { i[n] } -> const ValueType<I> &; });
 };
```

[Editor's note: Remove Table 111]

Let a and b be valid iterators of type I such that b is reachable from a. Let n be an object the smallest value of type DifferenceType<I> such that after n applications of ++a, (a == b) != false. Then I models RandomAccessIterator if and only if:

```
    (2.1) — (a += n) == is equal to b.
    (2.2) — &(a += n) == is equal to &a.
    (2.3) — (a + n) == is equal to (a += n).
    (2.4) — For any two positive integers x and y, if a + (x + y) is valid, then a + (x + y) == is equal to (a + x) + y.
```

§ 24.2.19 30

```
(2.5) — a + 0 == is equal to a.

(2.6) — If (a + (n - 1)) is valid, then a + n == is equal to ++(a + (n - 1)).

(2.7) — (b += -n) == is equal to a.

(2.8) — (b -= n) == is equal to a.

(2.9) — &(b -= n) == is equal to &b.

(2.10) — (b - n) == is equal to (b -= n).

(2.11) — If b is dereferenceable, then a[n] is valid and is equal to *b.
```

#### 24.3 Indirect callable requirements

[indirect callables]

#### 24.3.1 In general

#### [indirect callables.general]

<sup>1</sup> There are several concepts that group requirements of algorithms that take callable objects (20.9.2) as arguments.

[Editor's note: Specifying the algorithms in terms of these indirect callable concepts would ease the transition should we ever decide to support proxy iterators in the future. See the Future Work appendix (C.3).]

#### 24.3.2 Function type

#### [functiontype.indirectcallables]

<sup>1</sup> The FunctionType is an alias used to turn a callable type (20.9.1) into a function object type (20.9).

```
// Exposition only
template <class T>
auto __as_fun_obj(T&& t, std::true_type) {
    return mem_fn(t);
}
template <class T>
T __as_fun_obj(T&& t, std::false_type) {
    return forward<T>(t);
}

template <class T>
using FunctionType =
    decltype(_as_fun_obj(declval<T>(), is_member_pointer<decay_t<T>>{}));
```

#### 24.3.3 Projected iterator

#### [projected.indirectcallables]

<sup>1</sup> The Projected class template is intended for use when specifying the constraints of algorithms that accept callable objects and projections. It bundles a Readable type I and a projection function Proj into a new Readable type whose reference type is the result of applying Proj to the ReferenceType of I.

```
template <Readable I, class Proj>
  requires RegularFunction<FunctionType<Proj>, ValueType<I>>
struct Projected {
  using difference_type = DifferenceType<I>;
  using value_type = decay_t<ResultType<FunctionType<Proj>, ValueType<I>>>;
  ResultType<FunctionType<Proj>, ReferenceType<I>> operator*() const;
};

template <WeaklyIncrementable I, class Proj>
struct difference_type<Projected<I, Proj>> {
  using type = DifferenceType<I>;
};
```

§ 24.3.3

2 [Note: Projected is only used to ease constraints specification. Its member function need not be defined. end note]

#### 24.3.4 Indirect callables

# [indirectfunc.indirectcallables]

<sup>1</sup> The indirect callable concepts are used to constrain those algorithms that accept callable objects (20.9.1) as arguments.

```
template <class F, class...Is>
using IndirectCallableResultType =
  ResultType<FunctionType<F>, ValueType<Is>...>;
template <class F, class...Is>
concept bool IndirectCallable =
  (Readable<Is> && ...) &&
 Function<FunctionType<F>, ValueType<Is>...>;
template <class F, class...Is>
concept bool IndirectRegularCallable =
  (Readable<Is> && ...) &&
  RegularFunction<FunctionType<F>, ValueType<Is>...>;
template <class F, class...Is>
concept bool IndirectCallablePredicate =
  (Readable<Is> && ...) &&
  Predicate<FunctionType<F>, ValueType<Is>...>;
template <class F, class I1, class I2 = I1>
concept bool IndirectCallableRelation =
  Readable<I1> &&
  Readable<I2> &&
  Relation<FunctionType<F>, ValueType<I1>, ValueType<I2>>();
template <class F, class I1, class I2 = I1>
concept bool IndirectCallableStrictWeakOrder =
  Readable<I1> &&
  Readable<I2> &&
  StrictWeakOrder<FunctionType<F>, ValueType<I1>, ValueType<I2> >();
```

## 24.4 Common algorithm requirements

[commonalgoreq]

# 24.4.1 In general

### [commonalgoreq.general]

<sup>1</sup> There are several additional iterator concepts that are commonly applied to families of algorithms. These group together iterator requirements of algorithm families. There are four relational concepts for rearrangements: Permutable, Mergeable, MergeMovable, and Sortable. There is one relational concept for comparing values from different sequences: IndirectlyComparable.

### 24.4.2 Concept IndirectlyComparable [indirectlycomparable.commmonalgoreq]

The IndirectlyComparable concept specifies the common requirements of algorithms that compare values from two different sequences.

```
template <class I1, class I2, class R = equal_to<>, class P1 = identity,
  class P2 = identity>
concept bool IndirectlyComparable =
  IndirectCallableRelation<R, Projected<I1, P1>, Projected<I2, P2>>;
```

§ 24.4.2 32

## 24.4.3 Concept Permutable

# [permutable.commmonalgoreq]

<sup>1</sup> The Permutable concept specifies the common requirements of algorithms that reorder elements in place by moving or swapping them.

```
template <class I>
concept bool Permutable =
  ForwardIterator<I> &&
  Semiregular<ValueType<I>> &&
  IndirectlyMovable<I, I>;
```

[Editor's note: REVIEW: Semiregular here overconstrains by adding a default-constructibility requirement. See Appendix D of the "The Palo Alto" report for an alternate design.]

# 24.4.4 Concept Mergeable

# [mergeable.commmonalgoreq]

The Mergeable concept describes the requirements of algorithms that merge sorted sequences into an output sequence by copying elements.

```
template <class I1, class I2, class Out,
    class R = less<>, class P1 = identity, class P2 = identity>
concept bool Mergeable =
    InputIterator<I1> &&
    InputIterator<I2> &&
    WeaklyIncrementable<Out> &&
    IndirectlyCopyable<I1, Out> &&
    IndirectlyCopyable<I2, Out> &&
    IndirectlyCopyable<I1, T2, R, P1, P2>;
    IndirectCallableStrictWeakOrder<R, Projected<I1, P1>, Projected<I2, P2> >;
```

- <sup>2</sup> The relation R must represent a strict weak ordering.
- <sup>3</sup> [Note: When less<> is used as the relation, the value type must model TotallyOrdered. end note]

## 24.4.5 Concept MergeMovable

## [mergemovable.commmonalgoreq]

<sup>1</sup> The MergeMovable concept describes the requirements of algorithms that merge sorted sequences into an output sequence by moving elements.

```
template <class I1, class I2, class Out,
    class R = less<>, class P1 = identity, class P2 = identity>
concept bool MergeMovable =
    InputIterator<I1> &&
    InputIterator<I2> &&
    WeaklyIncrementable<Out> &&
    IndirectlyMovable<I1, Out> &&
    IndirectlyMovable<I2, Out> &&
    IndirectlyMovable<I2, P1, P2>;
    IndirectCallableStrictWeakOrder<R, Projected<I1, P1>, Projected<I2, P2> >;
```

- <sup>2</sup> The relation R must represent a strict weak ordering.
- <sup>3</sup> [Note: When less<> is used as the relation, the value type must model TotallyOrdered. end note]

### 24.4.6 Concept Sortable

[sortable.commmonalgoreq]

<sup>1</sup> The Sortable concept describes the common requirements of algorithms that permute sequences of iterators into an ordered sequence (e.g., sort).

```
template <class I, class R = less<>, class P = identity>
concept bool Sortable =
```

§ 24.4.6

```
ForwardIterator<I> &&
Permutable<I> &&
IndirectCallableRelationStrictWeakOrder<R, Projected<I, P>>;
```

- <sup>2</sup> The relation R must represent a strict weak ordering.
- <sup>3</sup> [Note: When less<> is used as the relation, the value type must model TotallyOrdered. end note]

#### 24.5 Iterator range requirements

[iteratorranges]

### 24.5.1 Concept SizedIteratorRange

[sizediteratorrange.iteratorranges]

The SizedIteratorRange concept describes the requirements on an Iterator (24.2.11) and a Sentinel that allows the use of the - operator to compute the distance between them in constant time.

```
template <class I, class S>
concept bool SizedIteratorRange =
  Sentinel<S, I> &&
  requires (I i, S j) {
      { i - i } -> DifferenceType<I>;
      { j - j } -> DifferenceType<I>;
      { i - j } -> DifferenceType<I>;
      { j - i } -> DifferenceType<I>;
      { j - i } -> DifferenceType<I>;
    };
```

Let a be a valid iterator of type I and b be a valid sentinel of type S. Let n be an object the smallest value of type DifferenceType<I> such that after n applications of ++a, (a == b) != false. Then types I and S model SizedIteratorRange if and only if:

```
(1.1) — (b - a) == n.
```

- (1.2) (a b) == -n.
- (1.3) (a a) == 0.
- (1.4) (b b) == 0.

[ Note: The SizedIteratorRange concept is modeled by pairs of RandomAccessIterators (24.2.19) and by counted iterators and their sentinels (24.8.6.1). —  $end\ note$  ]

[Editor's note: This concept also gives us a way to demote the category of move\_iterators to Input while retaining the ability of move\_iterator pairs to communicate the range's size to container constructors.]

# 24.6 Header <iterator> synopsis

[iterator.synopsis]

```
namespace std {
    // 24.7, primitives:
    template<class Iterator> structusing iterator_traits = see below;

## 24.7 Iterator primitives

}

[iterator.primitives]

<sup>1</sup> To simplify the task of defining iterators, the library provides several classes and functions:

### 24.7.1 Iterator traitsassociated types

[iterator.assoc]

To implement algorithms only in terms of iterators, it is often necessary to determine the value and difference types that correspond to a particular iterator type. Accordingly, it is required that if <a href="Iterator-is-the-type-of-an-iterator-WeaklyIncrementable">Iterator-is-the-type-of-an-iterator-WeaklyIncrementable</a> is the name of a type that models the Readable concept (24.2.8), Readable is the name of a type that models the Readable concept (24.2.2), and WeakInputIterator is the name of a type that models the WeakInputIterator (24.2.13) concept, the types

```
iterator_traits<Iterator>::difference_type
iterator_traits<Iterator>::value_type
iterator_traits<Iterator>::iterator_category

DifferenceType<WeaklyIncrementable>
ValueType<Readable>
IteratorCategory<WeakInputIterator>
```

be defined as the iterator's difference type, value type and iterator category, respectively. In addition, the types

ReferenceType<Readable>
shall be an alias for decltype(\*declval<Readable>()).
iterator\_traits<Iterator>::reference
iterator\_traits<Iterator>::pointer

§ 24.7.1 41

shall be defined as the iterator's reference and pointer types, that is, for an iterator object a, the same type as the type of \*a and a->, respectively. In the case of an output iterator, the types

```
iterator_traits<Iterator>::difference_type
    iterator_traits<Iterator>::value_type
    iterator_traits<Iterator>::reference
    iterator_traits<Iterator>::pointer
  may be defined as void.
<sup>2</sup> The template iterator traits<Iterator> is defined as
    namespace std {
      template<class Iterator> struct iterator_traits {
        typedef typename Iterator::difference_type difference_type;
        typedef typename Iterator::value_type value_type;
        typedef typename Iterator::pointer pointer;
        typedef typename Iterator::reference reference;
        typedef typename Iterator::iterator_category iterator_category;
      };
    }
<sup>3</sup> It is specialized for pointers as
    namespace std {
      template<class T> struct iterator_traits<T*> {
        typedef ptrdiff_t difference_type;
        typedef T value_type;
        typedef T* pointer;
        typedef T& reference;
        typedef random_access_iterator_tag iterator_category;
      };
    }
  and for pointers to const as
    namespace std {
      template<class T> struct iterator_traits<const T*> {
        typedef ptrdiff_t difference_type;
        typedef T value_type;
        typedef const T* pointer;
        typedef const T& reference;
        typedef random_access_iterator_tag iterator_category;
      };
    }
4 DifferenceType<T> is implemented as if:
      template <class, class = void> struct difference_type { };
      template <class T>
      struct difference_type<T*> : enable_if<is_object<I>::value, ptrdiff_t> { };
        using type = ptrdiff_t;
      <del>};</del>
      template <>
      struct difference_type<nullptr_t> {
        using type = ptrdiff_t;
      template <class T> struct difference_type<T[]> {
```

§ 24.7.1 42

```
using type = ptrdiff_t;
<del>};</del>
template <class T, size_t N> struct difference_type<T[N]> {
  using type = ptrdiff_t;
<del>};</del>
template <class I>
struct difference_type<I const> : difference_type<decay_t<I>> { };
template <class I>
struct difference_type<I volatile> : difference_type<decay_t<I>>> { };
template <class I>
struct difference_type<I const volatile> : difference_type<decay_t<I>>> { };
template <class T>
  requires requires { typename T::difference_type; }
struct difference type<T, void t<typename T::difference type>> {
 using type = typename T::difference_type;
};
template <class T>
 requires is_integral<T>()
struct difference_type<T, enable_if_t<is_integral<T>::value>>
  : make_signed< decltype(declval<T>() - declval<T>()) > {
};
template <class T>
  using DifferenceType = typename difference_type<T>::type;
```

[Editor's note: REVIEW: The difference\_type of unsigned Integral types is not large enough to cover the entire range. The Palo Alto report used a separate type trait for WeaklyIncrementable: DistanceType. DifferenceType is only used for RandomAccessIterators. Cue discussion about the pros and cons of the two approaches.]

- <sup>5</sup> Users may specialize difference\_type on user-defined types.
- <sup>6</sup> IteratorCategory<T> is implemented as if:

```
template <class, class = void> struct iterator_category { };
template <class T>
struct iterator_category<T*>
  : enable_if<is_object<T>::value, random_access_iterator_tag> { };
  using type = random_access_iterator_tag;
<del>};</del>
template <class T>
struct iterator_category<T const> : iterator_category<T> { };
template <class T>
struct iterator_category<T volatile> : iterator_category<T> { };
template <class T>
struct iterator_category<T const volatile> : iterator_category<T> { };
template <class T>
 requires requires { typename T::iterator_category; }
struct iterator_category<T, void_t<typename T::iterator_category>> {
 using type = typename T::iterator_category;
};
template <class T>
 using IteratorCategory = typename iterator_category<T>::type;
```

- <sup>7</sup> Users may specialize iterator\_category on user-defined types.
- <sup>8</sup> [Note: If there is an additional pointer type \_\_far such that the difference of two \_\_far is of type long, an implementation may define

§ 24.7.1 43

```
template<class T> struct iterator_traits<T __far*> {
         typedef long difference_type;
         typedef T value_type;
         typedef T __far* pointer;
         typedef T __far& reference;
         typedef random_access_iterator_tag iterator_category;
       };
    - end note
9 For the sake of backwards compatibility, this standard specifies the existence of an iterator_traits alias
   that collects an iterator's associated types. It is defined as if:
       template <WeakInputIterator I, class = void> struct __pointer_type {
         using type = add_pointer_t<ReferenceType<I>>;
       };
       template <WeakInputIterator I>
         requires requires(I i) { { i.operator->() } -> auto&&; }
       struct __pointer_type<I, void_t<decltype(declval<I>().operator->())>> {
         using type = decltype(declval<I>().operator->());
       template <class> struct __iterator_traits { };
       template <WeakIterator I> struct __iterator_traits<I> {
         using difference_type = DifferenceType<I>;
         using value_type = void;
         using reference = void;
         using pointer = void;
         using iterator_category = output_iterator_tag;
       };
       template <WeakInputIterator I> struct __iterator_traits<I> {
         using difference_type = DifferenceType<I>;
         using value_type = ValueType<I>;
         using reference = ReferenceType<I>;
         using pointer = typename __pointer_type<I>::type;
         using iterator_category = IteratorCategory<I>;
       template <class I>
         using iterator_traits = __iterator_traits<I>;
<sup>10</sup> [Note: iterator_traits is a template alias to intentionally break code that tries to specialize it. — end
   note
11 [Example: To implement a generic reverse function, a C++ program can do the following:
     template <<del>class</del> BidirectionalIterator I>
     void reverse(BidirectionalIterator I first, BidirectionalIterator I last) {
       typename iterator_traits<BidirectionalIterator>::difference_typeDifferenceType<I> n =
         distance(first, last);
       --n:
       while(n > 0) {
         typename iterator_traits<BidirectionalIterator>::value_typeValueType<I>
           tmp = *first;
         *first++ = *--last;
         *last = tmp;
         n = 2;
       }
     }
   § 24.7.1
                                                                                                        44
```

— end example]

### 24.7.2 Basic iterator

[iterator.basic]

<sup>1</sup> The iterator template may be used as a base class to ease the definition of required types for new iterators.

2 [Note: The Pointer and Reference template parameters, and the nested pointer and reference type aliases are for backward compatibility only; they are never used by any other part of this standard. — end note]

# 24.7.3 Standard iterator tags

[std.iterator.tags]

It is often desirable for a function template specialization to find out what is the most specific category of its iterator argument, so that the function can select the most efficient algorithm at compile time. To facilitate this, the library introduces category tag classes which arecan be used as compile time tags for algorithm selection. [Note: The preferred way to dispatch to more specialized algorithm implementations is with concept-based overloading.—end note] They The category tags are: weak\_input\_iterator\_tag, input\_iterator\_tag, output\_iterator\_tag, forward\_iterator\_tag, bidirectional\_iterator\_tag and random\_access\_iterator\_tag. For every weak input iterator of type Iterator, iterator\_traits<Iterator>::iterator\_categoryIteratorCategory<Iterator> shall be defined to be the most specific category tag that describes the iterator's behavior.

```
namespace std {
    struct weak_input_iterator_tag { };
    struct input_iterator_tag: public weak_input_iterator_tag { };
    struct output_iterator_tag { };
    struct forward_iterator_tag: public input_iterator_tag { };
    struct bidirectional_iterator_tag: public forward_iterator_tag { };
    struct random_access_iterator_tag: public bidirectional_iterator_tag { };
}
```

- <sup>2</sup> [Note: The output\_iterator\_tag is provided for the sake of backward compatibility. end note]
- <sup>3</sup> [Example: For a program-defined iterator BinaryTreeIterator, it could be included into the bidirectional iterator category by specializing the <a href="mailto:iterator\_traits">iterator\_traits</a>difference\_type, value\_type, and <a href="mailto:iterator\_category">iterator\_category</a> templates:

```
template<class T> struct iterator_traits<BinaryTreeIterator<T> > {
   typedef std::ptrdiff_t difference_type;
   typedef T value_type;
   typedef T* pointer;
   typedef T& reference;
   typedef bidirectional_iterator_tag iterator_category;
};
```

§ 24.7.3 45

```
template<class T> struct difference_type<BinaryTreeIterator<T> > {
      using type = std::ptrdiff_t;
    };
    template<class T> struct value_type<BinaryTreeIterator<T> > {
      using type = T;
    };
    template<class T> struct iterator_category<BinaryTreeIterator<T> > {
      using type = bidirectional_iterator_tag;
    };
  Typically, however, it would be easier to derive BinaryTreeIterator<T> from iterator<br/>bidirectional_-
  iterator_tag,T,ptrdiff_t<del>,T*,T&</del>>. — end example]
<sup>4</sup> [Example: If evolve() is well defined for bidirectional iterators, but can be implemented more efficiently
  for random access iterators, then theone possible implementation is as follows:
    template <class BidirectionalIterator>
    inline void
    evolve(BidirectionalIterator first, BidirectionalIterator last) {
      evolve(first, last,
        typename iterator traits < Bidirectional Iterator >::iterator category()
         IteratorCategory<BidirectionalIterator>{});
    }
    template <class BidirectionalIterator>
     void evolve(BidirectionalIterator first, BidirectionalIterator last,
      bidirectional_iterator_tag) {
      // more generic, but less efficient algorithm
    template <class RandomAccessIterator>
    void evolve(RandomAccessIterator first, RandomAccessIterator last,
```

- end example]

<sup>5</sup> [Example: If a C++ program wants to define a bidirectional iterator for some data structure containing double and such that it works on a large memory model of the implementation, it can do so with:

```
class MyIterator :
  public iterator<bidirectional_iterator_tag, double, long, T*, T%> {
    // code implementing ++, etc.
};
```

Then there is no need to specialize the <u>iterator\_traits</u>difference\_type, <u>value\_type</u>, <u>or iterator\_category</u> templates. — end example]

### 24.7.4 Iterator operations

random\_access\_iterator\_tag) {

// more efficient, but less generic algorithm

[iterator.operations]

Since only random access iterators models of RandomAccessIterator provide the + and operator, and models of SizedIteratorRange provide the - operators, the library provides two function templates advance and distance. These function templates use + and - for random access iterators and sized iterator ranges, respectively (and are, therefore, constant time for them); for input, forward and bidirectional iterators they use ++ to provide linear time implementations.

template <class InputIterator, class Distance>

§ 24.7.4 46

```
void advance(InputIterator& i, Distance n);
            template <WeakIterator I>
                 void advance(I& i, DifferenceType<I> n);
       2
                        Requires: n shall be negative only for bidirectional and random access iterators.
       3
                       Effects: Increments (or decrements for negative n) iterator reference i by n.
            template <Iterator I, Sentinel<I> S>
                void advance(I& i, S bound);
       4
                        Requires: bound shall be reachable from i.
       5
                        Effects: Increments iterator reference i until i == bound.
       6
                       If I and S are the same type, this function is constant time.
       7
                       If I and S model the concept SizedIteratorRange, this function shall dispatch to advance(i, bound
                       - i).
            template <Iterator I, Sentinel<I> S>
                DifferenceType<I> advance(I& i, DifferenceType<I> n, S bound);
       8
                        Requires: n shall be negative only for bidirectional and random access iterators. If n is negative, i
                       shall be reachable from bound; otherwise, bound shall be reachable from i.
       9
                        Effects: Increments (or decrements for negative n) iterator reference i either n times or until i ==
                       bound, whichever comes first.
     10
                       If I and S model SizedIteratorRange:
(10.1)
                          — If (0 \le n ? n \ge D : n \le D) is true, where D is bound - i, this function dispatches to
                                 advance(i, bound),
(10.2)

    Otherwise, this function dispatches to advance(i, n).

     11
                        Returns: n - M, where M is the distance from the starting position of i to the ending position.
                 template<class InputIterator>
                         typename iterator_traits<InputIterator>::difference_type
                               distance(InputIterator first, InputIterator last);
            template <Iterator I, Sentinel<I> S>
                DifferenceType<I> distance(I first, S last);
     12
                        Effects: If \frac{InputIterator}{I} and S \frac{In
                       returns (last - first); otherwise, returns the number of increments needed to get from first to
                       last.
     13
                       Requires: If InputIterator I and S meets the requirements of random access iterator model SizedIterator Range,
                       last shall be reachable from first or first shall be reachable from last; otherwise, last shall be
                       reachable from first.
            template <class ForwardIterator>
                ForwardIterator next(ForwardIterator x,
                    typename std::iterator_traits<ForwardIterator>::difference_type n = 1);
            template <WeakIterator I>

17
         Effects: Equivalent to advance(x, -n); return x;
   template <BidirectionalIterator I>
     I prev(I x, DifferenceType<I> n, I bound);
         Effects: Equivalent to advance(x, -n, bound); return x;
```

### 24.8 Iterator adaptors

[predef.iterators]

### 24.8.1 Reverse iterators

[reverse.iterators]

Class template reverse\_iterator is an iterator adaptor that iterates from the end of the sequence defined by its underlying iterator to the beginning of that sequence. The fundamental relation between a reverse iterator and its corresponding iterator i is established by the identity: &\*(reverse\_iterator(i)) == &\*(i - 1).

### 24.8.1.1 Class template reverse\_iterator

[reverse.iterator]

```
namespace std {
 template <class IteratorBidirectionalIterator I>
 class reverse_iterator : public{
        iterator<typename iterator_traits<Iterator>::iterator_category,
        typename iterator_traits<Iterator>::value_type,
        typename iterator_traits<Iterator>::difference_type,
        typename iterator_traits<Iterator>::pointer,
        typename iterator_traits<Iterator>::reference> {
  public:
    typedef Iterator
                                                                iterator_type;
    typedef typename iterator_traits<Iterator>::difference_type difference_type;
    typedef typename iterator_traits<Iterator>::reference
                                                                reference;
    typedef typename iterator_traits<Iterator>::pointer
                                                                pointer;
    using iterator_type = I;
    using difference_type = DifferenceType<I>;
    using value_type = ValueType<I>;
    using iterator_category = IteratorCategory<I>;
    using reference = ReferenceType<I>;
    using pointer = I;
```

  24.8.1.2 reverse_iterator requirements
                                                                                    [reverse.iter.requirements]
<sup>1</sup> The template parameter Iterator shall meet all the requirements of a Bidirectional Iterator (24.2.18).
<sup>2</sup> Additionally, Iterator shall meet the requirements of a Random Access Iterator (24.2.19) if any of the mem-
  bers operator+ (24.8.1.3.8), operator- (24.8.1.3.10), operator+= (24.8.1.3.9), operator-= (24.8.1.3.11),
  operator [] (24.8.1.3.12), or the global operators operator (24.8.1.3.14), operator (24.8.1.3.16),
  operator \leq (24.8.1.3.18), operator \geq (24.8.1.3.17), operator \leq (24.8.1.3.19) or operator \leq (24.8.1.3.20) are
  referenced in a way that requires instantiation (14.7.1).
  24.8.1.3 reverse_iterator operations
                                                                                               [reverse.iter.ops]
                                                                                              [reverse.iter.cons]
  24.8.1.3.1 reverse iterator constructor
  reverse_iterator();
         Effects: Value initializes current. Iterator operations applied to the resulting iterator have defined
        behavior if and only if the corresponding operations are defined on a value-initialized iterator of type
        IteratorI.If I is a literal type, then this constructor shall be a trivial constructor.
  explicit reverse_iterator(IteratorI x);
         Effects: Initializes current with x.
  template <<del>class</del>BidirectionalIterator U>
     requires Convertible<U, I>
  reverse_iterator(const reverse_iterator<U>& u);
         Effects: Initializes current with u.current.
  24.8.1.3.2 reverse_iterator::operator=
                                                                                              [reverse.iter.op=]

```

§ 24.8.1.3.21 53

#### 24.8.2 Insert iterators

[insert.iterators]

<sup>1</sup> To make it possible to deal with insertion in the same way as writing into an array, a special kind of iterator adaptors, called *insert iterators*, are provided in the library. With regular iterator classes,

```
while (first != last) *result++ = *first++;
```

causes a range [first,last) to be copied into a range starting with result. The same code with result being an insert iterator will insert corresponding elements into the container. This device allows all of the copying algorithms in the library to work in the *insert mode* instead of the *regular overwrite* mode.

An insert iterator is constructed from a container and possibly one of its iterators pointing to where insertion takes place if it is neither at the beginning nor at the end of the container. Insert iterators satisfy the requirements of output iterators. operator\* returns the insert iterator itself. The assignment operator=(const T& x) is defined on insert iterators to allow writing into them, it inserts x right before where the insert iterator is pointing. In other words, an insert iterator is like a cursor pointing into the container where the insertion takes place. back\_insert\_iterator inserts elements at the end of a container, front\_insert\_-iterator inserts elements at the beginning of a container, and insert\_iterator inserts elements where the iterator points to in a container. back\_inserter, front\_inserter, and inserter are three functions making the insert iterators out of a container.

## 24.8.2.1 Class template back\_insert\_iterator

[back.insert.iterator]

[Editor's note: REVIEW: Re-specify this in terms of a Container concept? Or Range? Or leave it?]

```
namespace std {
   template <class Container>
   class back_insert_iterator +{
     public iterator<output_iterator_tag,void,void,void> }
   protected:
      Container* container;
   public:
     typedef Containerusing container_type = Container;
      using difference_type = ptrdiff_t;
      using iterator_category = output_iterator_tag;
      back_insert_iterator();
      explicit back_insert_iterator(Container& x);
      back_insert_iterator<Container>&
       operator=(const typename Container::value_type& value);
      back_insert_iterator<Container>&
       operator=(typename Container::value_type&& value);
     back_insert_iterator<Container>& operator*();
     back_insert_iterator<Container>& operator++();
     back_insert_iterator<Container> operator++(int);
   };
   template <class Container>
     back_insert_iterator<Container> back_inserter(Container& x);
  }
24.8.2.2 back insert iterator operations
                                                                              [back.insert.iter.ops]
                                                                            [back.insert.iter.cons]
24.8.2.2.1 back_insert_iterator constructor
back_insert_iterator();
```

§ 24.8.2.2.1 54

```
Effects: Value-initializes container. This constructor shall be a trivial constructor.
  explicit back_insert_iterator(Container& x);
        Effects: Initializes container with std::addressof(x).
  24.8.2.2.2 back_insert_iterator::operator=
                                                                               [back.insert.iter.op=]

        insert_iterator<Container> inserter(Container& x, typename Container::iterator i);
    }
                                                                                       [insert.iter.ops]
  24.8.2.6 insert_iterator operations
  24.8.2.6.1 insert_iterator constructor
                                                                                      [insert.iter.cons]
  insert_iterator();
        Effects: Value-initializes container and iter. If Container::iterator is a literal type, then this
       constructor shall be a trivial constructor.
  insert_iterator(Container& x, typename Container::iterator i);
        Effects: Initializes container with std::addressof(x) and iter with i.
  24.8.2.6.2 insert_iterator::operator=
                                                                                      [insert.iter.op=]
  insert_iterator<Container>&
    operator=(const typename Container::value_type& value);
1
        Effects:
          iter = container->insert(iter, value);
          ++iter;
        Returns: *this.
  insert iterator<Container>&
    operator=(typename Container::value_type&& value);
3
        Effects:
          iter = container->insert(iter, std::move(value));
          ++iter:
4
        Returns: *this.
```

§ 24.8.2.6.2

```
24.8.2.6.3 insert_iterator::operator*
                                                                                         [insert.iter.op*]
  insert_iterator<Container>& operator*();
1
        Returns: *this.
  24.8.2.6.4 insert_iterator::operator++
                                                                                      [insert.iter.op++]
  insert_iterator<Container>& operator++();
  insert_iterator<Container>& operator++(int);
        Returns: *this.
  24.8.2.6.5 inserter
                                                                                                [inserter]
  template <class Container>
    insert_iterator<Container> inserter(Container& x, typename Container::iterator i);
        Returns: insert_iterator<Container>(x, i).
  24.8.3
           Move iterators
                                                                                       [move.iterators]
<sup>1</sup> Class template move_iterator is an iterator adaptor with the same behavior as the underlying iterator
  except that its indirection operator implicitly converts the value returned by the underlying iterator's indi-
  rection operator to an rvalue reference. Some generic algorithms can be called with move iterators to replace
  copying with moving. [Editor's note: This is untrue now. The algorithms that do copying are constrained
  with IndirectlyCopyable, which will reject move_iterators.]
<sup>2</sup> [Example:
    list<string> s;
    // populate the list s
    vector<string> v1(s.begin(), s.end());
                                                      // copies strings into v1
    vector<string> v2(make_move_iterator(s.begin()),

        Returns: x + n.
  template <class IteratorWeakInputIterator I>
    move_iterator<\frac{Iterator}{Iterator} i);</pre>
        Returns: move iterator < Iterator I > (i).
  24.8.4 Common iterators
                                                                                    [common.iterators]
<sup>1</sup> Class template common iterator is an iterator/sentinel adaptor that is capable of representing a non-
  bounded range of elements (where the types of the iterator and sentinel differ) as a bounded range (where
  they are the same). It does this by holding either an iterator or a sentinel, and implementing the equality
  comparison operators appropriately.
<sup>2</sup> [Note: The common_iterator type is useful for interfacing with legacy code that expects the begin and
  end of a range to have the same type, and for use in common_type specializations that are required to make
  iterator/sentinel pairs model the EqualityComparable concept. — end note]
3 [Example:
    template < class ForwardIterator>
    void fun(ForwardIterator begin, ForwardIterator end);
    list<int> s;
     // populate the list s
    using CI =
      common_iterator<counted_iterator<list<int>::iterator>,
                       counteddefault_sentinel>;
     // call fun on a range of 10 ints
    fun(CI(make_counted_iterator(s.begin(), 10)),
        CI(counteddefault_sentinel()));
```

63

§ 24.8.4

— end example]

```
24.8.4.1 Class template common_iterator

      DifferenceType<I2> operator-(
        const common_iterator<I1, S1>& x, const common_iterator<I2, S2>& y);
<sup>1</sup> [Note: The use of the expository __WeaklyEqualityComparable and __WeakSentinel concepts is avoid
  the self-referential requirements that would happen if parameters I and S use common_iterator<I, S> as
  their common type. — end note]
<sup>2</sup> [Note: The ad hoc constraints on common_iterator's operator- exist for the same reason. — end note]
<sup>3</sup> [Note: It is unspecified whether common iterator's members iter and sent have distinct addresses or
  not. - end note
                                                                                     [common.iter.ops]
  24.8.4.2 common_iterator operations
                                                                                [common.iter.op.const]
  24.8.4.2.1 common_iterator constructors
  common_iterator();
        Effects: Constructs a common_iterator, value-initializing is_sentinel and iter. It is unspecified
        whether any initialization is performed for sent. Iterator operations applied to the resulting iterator
        have defined behavior if and only if the corresponding operations are defined on a value-initialized
        iterator of type I.
  common_iterator(I i);
        Effects: Constructs a common_iterator, initializing is_sentinel with false and iter with i. It is
        unspecified whether any initialization is performed for sent.
  common_iterator(S s);
        Effects: Constructs a common_iterator, initializing is_sentinel with true and sent with s. It is
        unspecified whether any initialization is performed for iter.
  template <InputIterator U, __WeakSentinel<U> V>
    requires Convertible<U, I> && Convertible<V, S>
  common_iterator(const common_iterator<U, V>& u);
        Effects: Constructs a common_iterator, initializing is_sentinel with u.is_sentinel.
```

65

— If u.is\_sentinel is true, sent is initialized with u.sent. It is unspecified whether any initial-

(4.1)

```
ization is performed for iter.
(4.2)
            — If u.is sentinel is false, iter is initialized with u.iter. It is unspecified whether any initial-
               ization is performed for sent.
     24.8.4.2.2
                common iterator::operator=
                                                                                      [common.iter.op=]

  24.8.5 Default sentinels
                                                                                  [default.sentinels]
  24.8.5.1 Class default sentinel
                                                                                         [default.sent]
  namespace std {
    class default_sentinel { };
  Class default_sentinel is an empty type used to denote the end of a range. It is intended to be used
  together with iterator types that know the bound of their range (e.g., counted_iterator (24.8.6.1)).
  24.8.5.2 default_sentinel operations
                                                                                     [default.sent.ops]
  24.8.5.2.1 default sentinel comparisons
                                                                               [default.sent.op.comp]
  constexpr bool operator==(default_sentinel x, default_sentinel y) noexcept;
       Returns: true
  constexpr bool operator!=(default_sentinel x, default_sentinel y) noexcept;
        Returns: false
  constexpr bool operator<(default_sentinel x, default_sentinel y) noexcept;</pre>
3
       Returns: false
  constexpr bool operator<=(default_sentinel x, default_sentinel y) noexcept;</pre>
                                                                                                     67
  § 24.8.5.2.1
```

```
Returns: true
  constexpr bool operator>(default_sentinel x, default_sentinel y) noexcept;
        Returns: false
  constexpr bool operator>=(default_sentinel x, default_sentinel y) noexcept;
        Returns: true
  24.8.5.2.2 default_sentinel non-member functions
                                                                             [default.sent.nonmember]
  constexpr ptrdiff_t operator-(default_sentinel x, default_sentinel y) noexcept;
        Returns: 0
  24.8.6 Counted iterators
                                                                                   [counted.iterators]
<sup>1</sup> Class template counted_iterator is an iterator adaptor with the same behavior as the underlying iterator
  except that it keeps track of its distance from its starting position. It can be used together with class
  counteddefault_sentinel in calls to generic algorithms to operate on a range of N elements starting at a
  given position without needing to know the end position a priori.
<sup>2</sup> [Example:
    list<string> s;
    // populate the list s
    vector<string> v(make_counted_iterator(s.begin(), 10),
                      counteddefault_sentinel()); // copies 10 strings into v
   — end example]
                                                                                      [counted.iterator]
  24.8.6.1 Class template counted_iterator

```

§ 24.8.6.2.14 75

#### 24.8.6.3 Counted sentinel

[counted.sentinel]

Class counted\_sentinel is an empty type used to represent the end of a counted range. It is used together with class template counted\_iterator (24.8.6.1) to denote a range of elements that starts at a known position and includes the subsequent N elements.

```
namespace std {
  class counted_sentinel { };
24.8.6.4
         Specializations of common_type
                                                                     [counted.traits.specializations]
namespace std {
 template<WeakInputIterator I>
 struct common_type<counted_iterator<I>, counteddefault_sentinel> {
    using type = common_iterator<counted_iterator<I>, counteddefault_sentinel>;
  template<WeakInputIterator I>
 struct common_type<<del>counteddefault</del>_sentinel, counted_iterator<I>>> {
    using type = common_iterator<counted_iterator<I>, counteddefault_sentinel>;
 };
7
     Note: By specializing common_type this way, counted_iterator and counteddefault_sentinel can
     satisfy the Common requirement of the EqualityComparable concept. — end note]
```

### 24.8.7 Unreachable sentinel

[unreachable.sentinels]

#### 24.8.7.1 Class unreachable sentinel

[unreachable.sentinel]

Class unreachable is a sentinel type that can be used with any Iterator to denote an infinite range. Comparing an iterator for equality with an object of type unreachable always returns false.

```
[Example:
```

```
char* p;
// set p to point to a character buffer containing newlines
char* nl = find(p, unreachable(), '\n');
```

Provided a newline character really exists in the buffer, the use of unreachable above potentially make the call to find more efficient since the loop test against the sentinel does not require a conditional branch.

— end example ]

```
namespace std {
  class unreachable { };
  template <Iterator I>
     constexpr bool operator==(I const &, unreachable) noexcept;
  template <Iterator I>
     constexpr bool operator==(unreachable, I const &) noexcept;
  constexpr bool operator==(unreachable, unreachable) noexcept;
  template <Iterator I>
     constexpr bool operator!=(I const &, unreachable) noexcept;
  template <Iterator I>
     constexpr bool operator!=(unreachable, I const &) noexcept;
  constexpr bool operator!=(unreachable, unreachable) noexcept;
  constexpr bool operator!=(unreachable, unreachable) noexcept;
}
```

# 24.8.7.2 unreachable operations

24.8.7.2.1 operator==

[unreachable.sentinel.ops]
[unreachable.sentinel.op==]

§ 24.8.7.2.1 76

```
template <Iterator I>
    constexpr bool operator==(I const &, unreachable) noexcept;
  template <Iterator I>
    constexpr bool operator==(unreachable, I const &) noexcept;
        Returns: false.
  constexpr bool operator==(unreachable, unreachable) noexcept;
        Returns: true.
  24.8.7.2.2 operator!=
                                                                          [unreachable.sentinel.op!=]
  template <Iterator I>
    constexpr bool operator!=(I const & x, unreachable y) noexcept;
  template <Iterator I>
    constexpr bool operator!=(unreachable x, I const & y) noexcept;
  constexpr bool operator!=(unreachable x, unreachable y) noexcept;
        Returns: !(x == y)
  24.8.7.3
            Specializations of common_type
                                                                  [unreachable.traits.specializations]
  namespace std {
    template<Iterator I>
    struct common_type<I, unreachable> {
      using type = common_iterator<I, unreachable>;
    template<Iterator I>
    struct common_type<unreachable, I> {
      using type = common_iterator<I, unreachable>;
    };
  }
1
       Note: By specializing common_type this way, any iterator and unreachable can satisfy the Common
       requirement of the EqualityComparable concept. — end note]
```

### 24.9 Stream iterators

[stream.iterators]

<sup>1</sup> To make it possible for algorithmic templates to work directly with input/output streams, appropriate iterator-like class templates are provided.

[Example:

```
partial_sum(istream_iterator<double, char>(cin),
  istream_iterator<double, char>(),
  ostream_iterator<double, char>(cout, "\n"));
```

reads a file containing floating point numbers from cin, and prints the partial sums onto cout. -end example

# 24.9.1 Class template istream\_iterator

[istream.iterator]

The class template istream\_iterator is an input iterator (24.2.14) that reads (using operator>>) successive elements from the input stream for which it was constructed. After it is constructed, and every time ++ is used, the iterator reads and stores a value of T. If the iterator fails to read and store a value of T (fail() on the stream returns true), the iterator becomes equal to the end-of-stream iterator value. The constructor with no arguments istream\_iterator() always constructs an end-of-stream input iterator object, which is the only legitimate iterator to be used for the end condition. The result of operator\* on an end-of-stream

§ 24.9.1

iterator is not defined. For any other iterator value a const T& is returned. The result of operator-> on an end-of-stream iterator is not defined. For any other iterator value a const T\* is returned. ([Editor's note: Added back since N4382.]) The behavior of a program that applies operator++() to an end-of-stream iterator is undefined. It is impossible to store things into istream iterators.

<sup>2</sup> Two end-of-stream iterators are always equal. An end-of-stream iterator is not equal to a non-end-of-stream iterator. Two non-end-of-stream iterators are equal when they are constructed from the same stream.

```
namespace std {
    template <class T, class charT = char, class traits = char_traits<charT>,
        class Distance = ptrdiff_t>
    class istream_iterator+
      public iterator<input_iterator_tag, T, Distance, const T*, const T&> {
    public:
      typedef input_iterator_tag iterator_category;
      typedef Distance difference_type;
      typedef T value_type;
      typedef const T& reference;
      typedef const T* pointer;
      typedef charT char_type;
      typedef traits traits_type;
      typedef basic_istream<charT,traits> istream_type;
      see below istream_iterator();
      istream_iterator(istream_type& s);
      istream_iterator(const istream_iterator& x) = default;
     ~istream_iterator() = default;
      const T& operator*() const;
      const T* operator->() const; [Editor's note: Added back since N4382.]
      istream_iterator<T,charT,traits,Distance>& operator++();
      istream_iterator<T,charT,traits,Distance> operator++(int);
   private:
      basic_istream<charT,traits>* in_stream; // exposition only
      T value;
                                               // exposition only
    };
    template <class T, class charT, class traits, class Distance>
      bool operator == (const istream_iterator < T, charT, traits, Distance > & x,
              const istream_iterator<T,charT,traits,Distance>& y);
    template <class T, class charT, class traits, class Distance>
      bool operator!=(const istream_iterator<T,charT,traits,Distance>& x,
              const istream_iterator<T,charT,traits,Distance>& y);
 }
24.9.1.1
          istream_iterator constructors and destructor
                                                                              [istream.iterator.cons]
see below istream_iterator();
     Effects: Constructs the end-of-stream iterator. If T is a literal type, then this constructor shall be a
     constexpr constructor.
     Postcondition: in_stream == 0.
istream_iterator(istream_type& s);
     Effects: Initializes in_stream with &s. value may be initialized during construction or the first time it

is referenced.

```
Postcondition: in_stream == &s.
  istream_iterator(const istream_iterator& x) = default;
5
        Effects: Constructs a copy of x. If T is a literal type, then this constructor shall be a trivial copy
        constructor.
6
        Postcondition: in_stream == x.in_stream.
  ~istream_iterator() = default;
        Effects: The iterator is destroyed. If T is a literal type, then this destructor shall be a trivial destructor.
  24.9.1.2 istream_iterator operations
                                                                                  [istream.iterator.ops]
  const T& operator*() const;
1
        Returns: value.
  const T* operator->() const;
        Returns: &(operator*())std::addressof(operator*()).
        [Editor's note: Added back since N4382.]
  istream_iterator<T,charT,traits,Distance>& operator++();
3
        Requires: in_stream != 0.
4
        Effects: *in_stream >> value.
5
        Returns: *this.
  istream_iterator<T,charT,traits,Distance> operator++(int);
6
        Requires: in_stream != 0.
7
        Effects:
          istream_iterator<T,charT,traits,Distance> tmp = *this;
          *in_stream >> value;
          return (tmp);
  template <class T, class charT, class traits, class Distance>
    bool operator==(const istream_iterator<T,charT,traits,Distance> &x,
                     const istream_iterator<T,charT,traits,Distance> &y);
        Returns: x.in_stream == y.in_stream.
  template <class T, class charT, class traits, class Distance>
    bool operator!=(const istream_iterator<T,charT,traits,Distance> &x,
                     const istream_iterator<T,charT,traits,Distance> &y);
        Returns: !(x == y)
```

§ 24.9.1.2

## 24.9.2 Class template ostream iterator

# [ostream.iterator]

ostream\_iterator writes (using operator<<) successive elements onto the output stream from which it was constructed. If it was constructed with charT\* as a constructor argument, this string, called a *delimiter string*, is written to the stream after every T is written. It is not possible to get a value out of the output iterator. Its only use is as an output iterator in situations like

```
while (first != last)
      *result++ = *first++;
2 ostream_iterator is defined as:
    namespace std {
      template <class T, class charT = char, class traits = char_traits<charT> >
      class ostream_iterator:
        public iterator<output_iterator_tag, void, void, void> {
      public:
        typedef output_iterator_tag iterator_category;
        typedef ptrdiff_t difference_type;
        typedef charT char_type;
        typedef traits traits_type;
        typedef basic_ostream<charT,traits> ostream_type;
        constexpr ostream_iterator() noexcept;
        ostream_iterator(ostream_type& s);
        ostream_iterator(ostream_type& s, const charT* delimiter);
        ostream_iterator(const ostream_iterator<T,charT,traits>& x);
        ~ostream_iterator();
        ostream_iterator<T,charT,traits>& operator=(const T& value);
        ostream_iterator<T,charT,traits>& operator*();
        ostream_iterator<T,charT,traits>& operator++();
        ostream_iterator<T,charT,traits>& operator++(int);
        basic_ostream<charT,traits>* out_stream; // exposition only
        const charT* delim;
                                                    // exposition only
  24.9.2.1 ostream iterator constructors and destructor
                                                                            [ostream.iterator.cons.des]
  constexpr ostream_iterator() noexcept;
        Effects: Initializes out stream and delim with null.
  ostream_iterator(ostream_type& s);
2
        Effects: Initializes out stream with &s and delim with null.
  ostream_iterator(ostream_type& s, const charT* delimiter);
3
        Effects: Initializes out_stream with &s and delim with delimiter.
  ostream_iterator(const ostream_iterator& x);
4
        Effects: Constructs a copy of x.
  ~ostream_iterator();
5
        Effects: The iterator is destroyed.
  § 24.9.2.1
                                                                                                      80
```

```
ostream_iterator& operator=(const T& value);

Effects:
    *out_stream << value;
    if(delim != 0)
        *out_stream << delim;
    return (*this);

Requires: out_stream!= 0.

ostream_iterator& operator*();</pre>
```

ostream iterator operations

3 Returns: \*this.

ostream\_iterator& operator++();
ostream\_iterator& operator++(int);

4 Returns: \*this.

# 24.9.3 Class template istreambuf\_iterator

[istreambuf.iterator]

[ostream.iterator.ops]

- The class template <code>istreambuf\_iterator</code> defines an input iterator (24.2.14) that reads successive characters from the streambuf for which it was constructed. <code>operator\*</code> provides access to the current input character, if any. <code>[Note: operator-> may return a proxy. end note]</code> ([Editor's note: Added back since N4382.]) Each time <code>operator++</code> is evaluated, the iterator advances to the next input character. If the end of stream is reached (<code>streambuf\_type::sgetc()</code> returns <code>traits::eof()</code>), the iterator becomes equal to the <code>end-of-stream</code> iterator value. The default constructor <code>istreambuf\_iterator()</code> and the constructor <code>istreambuf\_iterator()</code> both construct an end-of-stream iterator object suitable for use as an end-of-range. All specializations of <code>istreambuf\_iterator</code> shall have a trivial copy constructor, a <code>constexpr</code> default constructor, and a trivial destructor.
- <sup>2</sup> The result of operator\*() on an end-of-stream iterator is undefined. For any other iterator value a char\_-type value is returned. It is impossible to assign a character via an input iterator.

```
namespace std {
  template<class charT, class traits = char_traits<charT> >
  class istreambuf_iterator
     : public iterator<input_iterator_tag, charT,</pre>
                       typename traits::off_type, unspecified, charT> {
 public:
    typedef input_iterator_tag iterator_category;
    typedef charT value_type;
    typedef typename traits::off_type difference_type;
    typedef charT reference;
    typedef unspecified pointer;
    typedef charT
                                           char_type;
    typedef traits
                                           traits_type;
    typedef typename traits::int_type
                                           int_type;
    typedef basic_streambuf<charT,traits> streambuf_type;
    typedef basic_istream<charT,traits>
                                           istream_type;
                                           // exposition only
    class proxy;
    constexpr istreambuf_iterator() noexcept;
    istreambuf_iterator(const istreambuf_iterator&) noexcept = default;
```

      template <class charT, class traits>
        bool operator == (const istreambuf_iterator < charT, traits > & a,
                const istreambuf_iterator<charT,traits>& b);
      template <class charT, class traits>
        bool operator!=(const istreambuf_iterator<charT,traits>& a,
                const istreambuf_iterator<charT,traits>& b);
    }
  24.9.3.1 Class template istreambuf_iterator::proxy
                                                                          [istreambuf.iterator::proxy]
    namespace std {
      template <class charT, class traits = char_traits<charT> >
      class istreambuf_iterator<charT, traits>::proxy { // exposition only
        charT keep_;
        basic_streambuf<charT,traits>* sbuf_;
        proxy(charT c, basic_streambuf<charT,traits>* sbuf)
          : keep_(c), sbuf_(sbuf) { }
      public:
        charT operator*() { return keep_; }
    }
1 Class istreambuf_iterator<charT, traits>::proxy is for exposition only. An implementation is permit-
  ted to provide equivalent functionality without providing a class with this name. Class istreambuf_-
  iterator<charT, traits>::proxy provides a temporary placeholder as the return value of the post-
  increment operator (operator++). It keeps the character pointed to by the previous value of the iterator for
  some possible future access to get the character.
  24.9.3.2
            istreambuf_iterator constructors
                                                                             [istreambuf.iterator.cons]
  constexpr istreambuf_iterator() noexcept;
        Effects: Constructs the end-of-stream iterator.
  istreambuf_iterator(basic_istream<charT,traits>& s) noexcept;
  istreambuf_iterator(basic_streambuf<charT,traits>* s) noexcept;
        Effects: Constructs an istreambuf_iterator<> that uses the basic_streambuf<> object *(s.rdbuf()),
        or *s, respectively. Constructs an end-of-stream iterator if s.rdbuf() is null.
  istreambuf_iterator(const proxy& p) noexcept;
        Effects: Constructs a istreambuf_iterator<> that uses the basic_streambuf<> object pointed to
        by the proxy object's constructor argument p.

§ 24.9.3.2

```
24.9.3.3 istreambuf_iterator::operator*
                                                                           [istreambuf.iterator::op*]
  charT operator*() const
        Returns: The character obtained via the streambuf member sbuf_->sgetc().
            istreambuf iterator::operator++
                                                                         [istreambuf.iterator::op++]
  istreambuf_iterator<charT,traits>&
      istreambuf_iterator<charT,traits>::operator++();
1
       Effects: sbuf_->sbumpc().
2
        Returns: *this.
  proxy istreambuf_iterator<charT,traits>::operator++(int);
3
        Returns: proxy(sbuf_->sbumpc(), sbuf_).
            istreambuf_iterator::equal
                                                                          [istreambuf.iterator::equal]
  24.9.3.5
  bool equal(const istreambuf_iterator<charT,traits>& b) const;
        Returns: true if and only if both iterators are at end-of-stream, or neither is at end-of-stream, regard-
       less of what streambuf object they use.
                                                                         [istreambuf.iterator::op==]
  24.9.3.6 operator==
  template <class charT, class traits>
    bool operator == (const istreambuf_iterator < charT, traits > & a,
                    const istreambuf_iterator<charT,traits>& b);
        Returns: a.equal(b).
  24.9.3.7 operator!=
                                                                          [istreambuf.iterator::op!=]
  template <class charT, class traits>
    bool operator!=(const istreambuf_iterator<charT,traits>& a,
                    const istreambuf_iterator<charT,traits>& b);
        Returns: !a.equal(b).
                                                                              [ostreambuf.iterator]
  24.9.4 Class template ostreambuf_iterator
    namespace std {
      template <class charT, class traits = char_traits<charT> >
      class ostreambuf_iterator +
        public iterator<output_iterator_tag, void, void, void, void> {
      public:
        typedef output_iterator_tag iterator_category;
        typedef ptrdiff_t difference_type;
        typedef charT
                                               char_type;
        typedef traits
                                              traits_type;
        typedef basic_streambuf<charT,traits> streambuf_type;
        typedef basic_ostream<charT,traits>
                                              ostream_type;
      public:
        constexpr ostreambuf_iterator() noexcept;
        ostreambuf_iterator(ostream_type& s) noexcept;
        ostreambuf_iterator(streambuf_type* s) noexcept;
        ostreambuf_iterator& operator=(charT c);
```

§ 24.9.4

ostreambuf\_iterator& operator\*();

```
ostreambuf_iterator& operator++();
        ostreambuf_iterator& operator++(int);
        bool failed() const noexcept;
      private:
                                                // exposition only
        streambuf_type* sbuf_;
      };
    }
<sup>1</sup> The class template ostreambuf_iterator writes successive characters onto the output stream from which
  it was constructed. It is not possible to get a character value out of the output iterator.
  24.9.4.1 ostreambuf_iterator constructors
                                                                                  [ostreambuf.iter.cons]
  constexpr ostreambuf_iterator() noexcept;
1
        Effects: Initializes sbuf_ with null.
  ostreambuf_iterator(ostream_type& s) noexcept;
2
        Requires: s.rdbuf() shall not null pointer.
3
        Effects: Initializes sbuf_ with s.rdbuf().
  ostreambuf_iterator(streambuf_type* s) noexcept;
4
        Requires: s shall not be a null pointer.
5
        Effects: Initializes sbuf_ with s.
  24.9.4.2 ostreambuf_iterator operations
                                                                                   [ostreambuf.iter.ops]
  ostreambuf_iterator<charT,traits>&
    operator=(charT c);
1
        Effects: If failed() yields false, calls sbuf_->sputc(c); otherwise has no effect.
2
        Requires: sbuf_ != 0.
3
        Returns: *this.
  ostreambuf_iterator<charT,traits>& operator*();
4
        Returns: *this.
  ostreambuf_iterator<charT,traits>& operator++();
  ostreambuf_iterator<charT,traits>& operator++(int);
        Returns: *this.
  bool failed() const noexcept;
        Returns: true if in any prior use of member operator=, the call to sbuf_->sputc() returned
        traits::eof(); or false otherwise.
        Requires: sbuf_ != 0.
```

	Subclause	Header(s)
24.10.2	Requirements	
??	IterableRange primitives	<iterator></iterator>
??	Predefined ranges	
??	Stream ranges	

Table 4 — Ranges library summary

# 24.10 Range concepts

[iterables]

#### 24.10.1 General

[iterables.general]

- $^{\, 1} \,$  This subclause describes components for dealing with ranges of elements.
- <sup>2</sup> The following subclauses describe <u>iterablerange</u> and <u>rangeview</u> requirements, and components for <u>iterablerange</u> primitives, predefined ranges, and stream ranges, as summarized in Table 4.

## 24.10.2 Range requirements

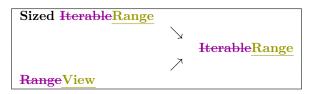

[iterables.requirements]

## 24.10.2.1 In general

[iterables.requirements.general]

- <sup>1</sup> Iterables Ranges are an abstraction of containers that allow a C++ program to operate on elements of data structures uniformly. It their simplest form, an iterable object is one on which one can call begin and end to get an iterator (24.2.11) and a sentinel (24.2.12) or an iterator. To be able to construct template algorithms and range adaptors that work correctly and efficiently on different types of sequences, the library formalizes not just the interfaces but also the semantics and complexity assumptions of iterables ranges.
- <sup>2</sup> This International Standard defines three fundamental categories of <u>iterablesranges</u> based on the syntax and semantics supported by each: <u>iterablerange</u>, <u>sized iterablesized range</u> and <u>rangeview</u>, as shown in Table 5.

Table 5 — Relations among iterablerange categories

- <sup>3</sup> The <u>IterableRange</u> concept requires only that begin and end return an iterator and a sentinel. [Note: An iterator is a valid sentinel. end note] The <u>SizedIterableSizedRange</u> concept refines <u>IterableRange</u> but adds the requirement that the number of elements in the <u>iterablerange</u> can be determined in constant time with the <u>size</u> function. The <u>RangeView</u> concept describes requirements on an <u>IterableRange</u> type with constant-time copy and assign operations.
- In addition to the three fundamental iterable range categories, this standard defines a number of convenience refinements of Iterable Range that group together requirements that appear often in the concepts, algorithms, and range views adaptors. Bounded iterables Bounded ranges are iterables ranges for which begin and end return objects of the same type. Random access iterables Random access ranges are iterables ranges for which begin returns a model of Random Access Iterator (24.2.19). The iterable range categories bidirectional iterables bidirection forward iterables forward ranges, input iterables input ranges and output iterables output ranges are defined similarly. [Note: There is no weak input iterables weak input ranges or weak output iterables weak output ranges because of the Equality Comparable requirement on iterators and sentinels. —end note [Editor's note: TODO: Rethink that because a weak input range would not require (strongly) incrementable iterators.]

§ 24.10.2.1 85

#### 24.10.2.2 Ranges

[iterable.iterables]

<sup>1</sup> The **IterableRange** concept defines the requirements of a type that allows iteration over its elements by providing a **begin** iterator and an **end** iterator or sentinel.

```
template <class T>
using IteratorType = decltype(begin(declval<T>()));

template <class T>
using SentinelType = decltype(end(declval<T>()));

template <class T>
concept bool IterableRange =
  requires(T t) {
    typename IteratorType<T>;
    typename SentinelType<T>;
    { begin(t) } -> IteratorType<T>;
    { end(t) } -> SentinelType<T>;
    requires Sentinel<SentinelType<T>, IteratorType<T>>;
};
```

begin and end are required to be amortized constant time. [Note: Most algorithms requiring this concept simply forward to an Iterator-based algorithm by calling begin and end. —end note]

#### 24.10.2.3 Sized ranges

[sized.iterables]

<sup>1</sup> The <u>SizedIterableSizedRange</u> concept describes the requirements of an <u>IterableRange</u> type that knows its size in constant time with the <u>size</u> function.

- <sup>2</sup> For any type T, is\_sized\_<u>iterable</u>range<T> derives from true\_type if T models \_\_Sized<u>IterableRange</u>Like, and false\_type otherwise.
- <sup>3</sup> Users are free to specialize is\_sized\_iterablerange. [Note: Users may want to specialize is\_sized\_iterablerange to override the default in the case of accidental conformance. end note]
- <sup>4</sup> [Note: A possible implementation for is sized iterablerange is given below:

```
template <class R>
struct is_sized_iterablerange : false_type { };

template <__Sized_IterableRangeLike R>
struct is_sized_iterablerange<R> : true_type { };

-- end note]
```

§ 24.10.2.3

24.10.2.4 Views [range.iterables]

<sup>1</sup> The RangeView concept describes the requirements of an IterableRange type that has constant time copy, move and assignment operators; that is, the cost of these operations is not proportional to the number of elements in the RangeView.

- <sup>2</sup> [Example: Examples of RangeViews are:
- (2.1) An IterableRange type that wraps a pair of iterators.
- (2.2) An IterableRange type that hold its elements by shared\_ptr and shares ownership with all its copies.
- (2.3) An IterableRange type that generates its elements on demand.

A container (23) is not a RangeView since copying the container copies the elements, which cannot be done in constant time.  $-end\ example$ 

```
template <class T>
concept bool RangeView =
   IterableRange<T> && Semiregular<T> && is_rangeview<T>::value;
```

- <sup>3</sup> Since the difference between <a href="IterableRange">IterableRange</a> and <a href="RangeView">RangeView</a> is largely semantic, the two are differentiated with the help of the <a href="is\_rangeview">is\_rangeview</a> trait. By default, <a href="is\_rangeview">is\_rangeview</a> trait.
- (3.1) If T derives from rangeview\_base, is\_rangeview<T>::value is true.
- (3.2) If a top-level const changes T's IteratorType's ReferenceType type, is\_rangeview<T>::value is false. [Note: Deep const-ness implies element ownership, whereas shallow const-ness implies reference semantics. end note]
  - <sup>4</sup> [Note: Below is a possible implementation of the is rangeview trait.

## 24.10.2.5 Bounded ranges

[bounded.iterables]

<sup>1</sup> The Bounded<del>IterableRange</del> concept describes requirements of an <del>IterableRange</del> type for which begin and end return objects of the same type. [Note: The standard containers (23) are models of Bounded<del>IterableRange</del>. — end note]

§ 24.10.2.5

```
template <class T>
         concept bool BoundedIterableRange =
            IterableRange<T> && Same<IteratorType<T>, SentinelType<T>>;
     24.10.2.6 Input ranges
                                                                                                                                                                         [input.iterables]
<sup>1</sup> The Input IterableRange concept describes requirements of an IterableRange type for which begin returns
     a model of InputIterator (24.2.14).
         template <class T>
         concept bool InputIterableRange =
            IterableRange<T> && InputIterator<IteratorType<T>>;
     24.10.2.7 Forward ranges
                                                                                                                                                                    [forward.iterables]
<sup>1</sup> The Forward<del>IterableRange</del> concept describes requirements of an Input<del>IterableRange</del> type for which
     begin returns a model of ForwardIterator (24.2.17).
         template <class T>
         concept bool ForwardIterableRange =
            InputIterableRange<T> && ForwardIterator<IteratorType<T>>;
     24.10.2.8 Bidirectional ranges
                                                                                                                                                          [bidirectional.iterables]
<sup>1</sup> The Bidirectional Iterable Range concept describes requirements of a Forward Iterable Range type for
     which begin returns a model of BidirectionalIterator (24.2.18).
         template <class T>
         concept bool Bidirectional Iterable Range =
            Forward <a href="Iterator">Iterator</a> <a href="Iterator">Ite
     24.10.2.9 Random access ranges
                                                                                                                                                      [random.access.iterables]
<sup>1</sup> The RandomAccess<del>IterableRange</del> concept describes requirements of a Bidirectional<del>IterableRange</del> type
     for which begin returns a model of RandomAccessIterator (24.2.19).
         template <class T>
         concept bool RandomAccessIterableRange =
            BidirectionalIterableRange<T> && RandomAccessIterator<IteratorType<T>>;
                                                                                                                                                                       [iterator.range]
     24.11
                     range access
<sup>1</sup> In addition to being available via inclusion of the <iterator> header, the function templates in 24.11 are
     available when any of the following headers are included: <array>, <deque>, <forward_list>, st>,
     <map>, <regex>, <set>, <string>, <unordered_map>, <unordered_set>, and <vector>.
     template <class C> auto begin(C& c) -> decltype(c.begin());
     template <class C> auto begin(const C& c) -> decltype(c.begin());
               Returns: c.begin().
     template <class C> auto end(C& c) -> decltype(c.end());
     template <class C> auto end(const C& c) -> decltype(c.end());
               Returns: c.end().
     template <class T, size_t N> constexpr T* begin(T (&array)[N]) noexcept;
               Returns: array.
```

§ 24.11 88

3

```
template <class T, size_t N> constexpr T* end(T (&array)[N]) noexcept;
5
        Returns: array + N.
   template <class C> constexpr auto cbegin(const C& c) noexcept(noexcept(std::begin(c)))
     -> decltype(std::begin(c));
        Returns: std::begin(c).
   template <class C> constexpr auto cend(const C& c) noexcept(noexcept(std::end(c)))
     -> decltype(std::end(c));
        Returns: std::end(c).
   template <class C> auto rbegin(C& c) -> decltype(c.rbegin());
   template <class C> auto rbegin(const C& c) -> decltype(c.rbegin());
        Returns: c.rbegin().
   template <class C> auto rend(C& c) -> decltype(c.rend());
   template <class C> auto rend(const C& c) -> decltype(c.rend());
        Returns: c.rend().
   template <class T, size_t N> reverse_iterator<T*> rbegin(T (&array)[N]);
10
         Returns: reverse_iterator<T*>(array + N).
   template <class T, size_t N> reverse_iterator<T*> rend(T (&array)[N]);
11
         Returns: reverse_iterator<T*>(array).
   template <class E> reverse_iterator<const E*> rbegin(initializer_list<E> il);
12
        Returns: reverse_iterator<const E*>(il.end()).
   template <class E> reverse_iterator<const E*> rend(initializer_list<E> il);
13
         Returns: reverse_iterator<const E*>(il.begin()).
   template <class C> auto crbegin(const C& c) -> decltype(std::rbegin(c));
14
        Returns: std::rbegin(c).
   template <class C> auto crend(const C& c) -> decltype(std::rend(c));
15
        Returns: std::rend(c).
```

§ 24.11 89

# 25 Algorithms library

# [algorithms]

#### 25.1 General

[algorithms.general]

<sup>1</sup> This Clause describes components that C++ programs may use to perform algorithmic operations on containers (Clause 23) and other sequences.

<sup>2</sup> The following subclauses describe components for non-modifying sequence operation, modifying sequence operations, sorting and related operations, and algorithms from the ISO C library, as summarized in Table 6.

Table 6 — Algorithms library summary

	Subclause	Header(s)
25.2	Non-modifying sequence operations	
25.3	Mutating sequence operations	<algorithm></algorithm>
25.4	Sorting and related operations	
25.5	C library algorithms	<cstdlib></cstdlib>

Editor's note: Remove the header <algorithm> synopsis. Header <algorithm> synopsis #include <initializer\_list> namespace std { // 25.2, non-modifying sequence operations: template<InputIterator I, Sentinel<I> S, class Proj = identity, IndirectCallablePredicate<Projected<I, Proj>> Pred> bool all\_of(I first, S last, Pred pred, Proj proj = Proj{}); template < Input Iterable Range Rng, class Proj = identity, IndirectCallablePredicate<Projected<IteratorType<Rng>, Proj>> Pred> bool all\_of(Rng&& rng, Pred pred, Proj proj = Proj{}); template<InputIterator I, Sentinel<I> S, class Proj = identity, IndirectCallablePredicate<Projected<I, Proj>> Pred> bool any\_of(I first, S last, Pred pred, Proj proj = Proj{}); template < Input Iterable Range Rng, class Proj = identity, IndirectCallablePredicate<Projected<IteratorType<Rng>, Proj>> Pred> bool any\_of(Rng&& rng, Pred pred, Proj proj = Proj{}); template<InputIterator I, Sentinel<I> S, class Proj = identity, IndirectCallablePredicate<Projected<I, Proj>> Pred> bool none\_of(I first, S last, Pred pred, Proj proj = Proj{}); template<Input\frac{IterableRange}{IterableRange} Rng, class Proj = identity,</pre> IndirectCallablePredicate<Projected<IteratorType<Rng>, Proj>> Pred> bool none\_of(Rng&& rng, Pred pred, Proj proj = Proj{}); template<InputIterator I, Sentinel<I> S, class Proj = identity,

```

- <sup>3</sup> All of the algorithms are separated from the particular implementations of data structures and are parameterized by iterator types. Because of this, they can work with program-defined data structures, as long as these data structures have iterator types satisfying the assumptions on the algorithms.
- <sup>4</sup> For purposes of determining the existence of data races, algorithms shall not modify objects referenced through an iterator argument unless the specification requires such modification.

Editor's note: The following paragraphs are removed because they are redundant; these requirements are

now enforced in code by the requires clauses.]

Throughout this Clause, the names of template parameters are used to express type requirements. If an algorithm's template parameter is InputIterator, InputIterator1, or InputIterator2, the actual template argument shall satisfy the requirements of an input iterator (24.2.14). If an algorithm's template parameter is OutputIterator, OutputIterator1, or OutputIterator2, the actual template argument shall satisfy the requirements of an output iterator (24.2.16). If an algorithm's template parameter is ForwardIterator, ForwardIterator1, or ForwardIterator2, the actual template argument shall satisfy the requirements of a forward iterator (24.2.17). If an algorithm's template parameter is BidirectionalIterator, BidirectionalIterator1, or BidirectionalIterator2, the actual template argument shall satisfy the requirements of a bidirectional iterator (24.2.18). If an algorithm's template parameter is RandomAccessIterator, RandomAccessIterator1, or RandomAccessIterator2, the actual template argument shall satisfy the requirements of a random-access iterator (24.2.19).

- <sup>6</sup> If an algorithm's **Effects** section says that a value pointed to by any iterator passed as an argument is modified, then that algorithm has an additional type requirement: The type of that argument shall satisfy the requirements of a mutable iterator (24.2). [Note: This requirement does not affect arguments that are declared as OutputIterator, OutputIterator1, or OutputIterator2, because output iterators must always be mutable. end note]
- <sup>7</sup> Both in-place and copying versions are provided for certain algorithms.<sup>2</sup> When such a version is provided for *algorithm* it is called *algorithm\_copy*. Algorithms that take predicates end with the suffix \_if (which follows the suffix \_copy).
- 8 The Predicate parameter is used whenever an algorithm expects a function object (20.9) that, when applied to the result of dereferencing the corresponding iterator, returns a value testable as true. In other words, if an algorithm takes Predicate pred as its argument and first as its iterator argument, it should work correctly in the construct pred(\*first) contextually converted to bool (Clause 4). The function object pred shall not apply any non-constant function through the dereferenced iterator.
- The BinaryPredicate parameter is used whenever an algorithm expects a function object that when applied to the result of dereferencing two corresponding iterators or to dereferencing an iterator and type T when T is part of the signature returns a value testable as true. In other words, if an algorithm takes BinaryPredicate binary\_pred as its argument and first1 and first2 as its iterator arguments, it should work correctly in the construct binary\_pred(\*first1, \*first2) contextually converted to bool (Clause 4). BinaryPredicate always takes the first iterator's value\_type as its first argument, that is, in those cases when T value is part of the signature, it should work correctly in the construct binary\_pred(\*first1, value) contextually converted to bool (Clause 4). binary\_pred shall not apply any non-constant function through the dereferenced iterators.
- 10 [Note: Projections and predicates are typically used as follows:

```
auto&& proj_ = callable(proj);
auto&& pred_ = callable(pred);
if(pred_(proj_(*first))) // ...
```

-end note

11 [Note: Unless otherwise specified, algorithms that take function objects as arguments are permitted to copy those function objects freely. Programmers for whom object identity is important should consider using a wrapper class that points to a noncopied implementation object such as reference\_wrapper<T> (20.9.3), or some equivalent solution. — end note]

<sup>2)</sup> The decision whether to include a copying version was usually based on complexity considerations. When the cost of doing the operation dominates the cost of copy, the copying version is not included. For example, sort\_copy is not included because the cost of sorting is much more significant, and users might as well do copy followed by sort.

When the description of an algorithm gives an expression such as \*first == value for a condition, the expression shall evaluate to either true or false in boolean contexts.

<sup>13</sup> In the description of the algorithms operators + and - are used for some of the iterator categories for which they do not have to be defined. In these cases the semantics of a+n is the same as that of

```
X tmp = a;
advance(tmp, n);
return tmp;
and that of b-a is the same as of
return distance(a, b);
```

<sup>14</sup> In the description of algorithm return values, sentinel values are sometimes returned where an iterator is expected. In these cases, the semantics are as if the sentinel is converted into an iterator as follows:

```
I tmp = first;
while(tmp != last)
    ++tmp;
return tmp;
```

Overloads of algorithms that take <a href="IterableRange">IterableRange</a> arguments (24.10.2.2) behave as if they are implemented by calling begin and end on the <a href="IterableRange">IterableRange</a> and dispatching to the overload that takes separate iterator and sentinel arguments.

## 25.2 Non-modifying sequence operations

[alg.nonmodifying]

## 25.2.1 All of

the projection.

2

[alg.all\_of]

```
template<class InputIterator, class Predicate>
bool all_of(InputIterator first, InputIterator last, Predicate pred);

template<InputIterator I, Sentinel<I> S, class Proj = identity,
    IndirectCallablePredicate<Projected<I, Proj>> Pred>
bool all_of(I first, S last, Pred pred, Proj proj = Proj{});

template<InputIterableRange Rng, class Proj = identity,
    IndirectCallablePredicate<Projected<IteratorType<Rng>, Proj>> Pred>
bool all_of(Rng&& rng, Pred pred, Proj proj = Proj{});

    Returns: true if [first,last) is empty or if pred(*i) INVOKE (pred, INVOKE (proj, *i)) is true for every iterator i in the range [first,last), and false otherwise.

Complexity: At most last - first applications of the predicate and last - first applications of
```

25.2.2 Any of [alg.any of]

```
template<class InputIterator, class Predicate>

  IteratorType<Rng1>
    find_end(Rng1& rng1, Rng2&& rng2, Pred pred = Pred{}, Proj proj = Proj{});
     Effects: Finds a subsequence of equal values in a sequence.
     Returns: The last iterator i in the range [first1,last1 - (last2 - first2)) such that for every
     non-negative integer n < (last2 - first2), the following corresponding conditions holds: *(i + n)
     == *(first2 + n), pred(*(i + n), *(first2 + n)) != false INVOKE(pred, INVOKE(proj, *(i
     + n)), *(first2 + n)) != false. Returns last1 if [first2,last2) is empty or if no such iterator
     is found.
     Complexity: At most (last2 - first2) * (last1 - first1 - (last2 - first2) + 1) applica-
     tions of the corresponding predicate and projection.
25.2.7 Find first
                                                                                  [alg.find.first.of]
template < class InputIterator, class ForwardIterator >
  InputIterator
    find_first_of(InputIterator first1, InputIterator last1,
                  ForwardIterator first2, ForwardIterator last2);
template < class InputIterator, class ForwardIterator,
          class BinaryPredicate>
  InputIterator
    find_first_of(InputIterator first1, InputIterator last1,
                  ForwardIterator first2, ForwardIterator last2,
                  BinaryPredicate pred);
template<InputIterator I1, Sentinel<I1> S1, ForwardIterator I2, Sentinel<I2> S2,
    class Proj1 = identity, class Proj2 = identity,
    IndirectCallablePredicate<Projected<I1, Proj1>, Projected<I2, Proj2>> Pred = equal_to<>>
    find_first_of(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = Pred{},
                  Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
template<Input IterableRange Rng1, Forward IterableRange Rng2, class Proj1 = identity,
    class Proj2 = identity,
    IndirectCallablePredicate<Projected<IteratorType<Rng1>, Proj1>,
     Projected<IteratorType<Rng2>, Proj2>> Pred = equal_to<>>
  IteratorType<Rng1>
    find_first_of(Rng1& rng1, Rng2&& rng2, Pred pred = Pred{},
                  Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
     Effects: Finds an element that matches one of a set of values.
     Returns: The first iterator i in the range [first1,last1) such that for some iterator j in the range
     [first2,last2) the following conditions holds: *i == *j, pred(*i,*j) != false INVOKE (pred,
     INVOKE (proj1, *i), INVOKE (proj2, *j)) != false. Returns last1 if [first2,last2) is empty
     or if no such iterator is found.
```

Complexity: At most (last1-first1) \* (last2-first2) applications of the corresponding predicate and the two projections.

```
25.2.8 Adjacent find
```

[alg.adjacent.find]

```
template < class ForwardIterator>
 ForwardIterator adjacent_find(ForwardIterator first, ForwardIterator last);
template<class ForwardIterator, class BinaryPredicate>
 ForwardIterator adjacent_find(ForwardIterator first, ForwardIterator last,
                              BinaryPredicate pred);
template<ForwardIterator I, Sentinel<I> S, class Proj = identity,
    IndirectCallableRelation<Projected<I, Proj>> Pred = equal_to<>>
  Т
    adjacent_find(I first, S last, Pred pred = Pred{},
                  Proj proj = Proj{});
template<Forward Iterable Range Rng, class Proj = identity,
    IndirectCallableRelation<Projected<IteratorType<Rng>, Proj>> Pred = equal_to<>>
  IteratorType<Rng>
    adjacent_find(Rng& rng, Pred pred = Pred{}, Proj proj = Proj{});
     Returns: The first iterator i such that both i and i + 1 are in the range [first,last) for which the
     following corresponding conditions holds: *i == *(i + 1), pred(*i, *(i + 1)) != false INVOKE (pred,
     INVOKE (proj, *i), INVOKE (proj, *(i + 1))) != false. Returns last if no such iterator is found.
     Complexity: For a nonempty range, exactly min((i - first) + 1, (last - first) - 1) applica-
     tions of the corresponding predicate, where i is adjacent_find's return value, and no more than twice
     as many applications of the projection.
25.2.9 Count
                                                                                          [alg.count]
template<class InputIterator, class T>
    typename iterator_traits<InputIterator>::difference_type
       count(InputIterator first, InputIterator last, const T& value);
template < class InputIterator, class Predicate >
    typename iterator_traits<InputIterator>::difference_type
      count_if(InputIterator first, InputIterator last, Predicate pred);
template<InputIterator I, Sentinel<I> S, class T, class Proj = identity>
  requires IndirectCallableRelation<equal_to<>, Projected<I, Proj>, const T *>
 DifferenceType<I>
    count(I first, S last, const T& value, Proj proj = Proj{});
template<Input\frac{IterableRange}{IterableRange} Rng, class T, class Proj = identity>
  requires IndirectCallableRelation<equal_to<>, Projected<IteratorType<Rng>, Proj>, const T *>
 DifferenceType<IteratorType<Rng>>
    count(Rng&& rng, const T& value, Proj proj = Proj{});
template<InputIterator I, Sentinel<I> S, class Proj = identity,
    IndirectCallablePredicate<Projected<I, Proj>> Pred>
 DifferenceType<I>
    count_if(I first, S last, Pred pred, Proj proj = Proj{});
template<InputIterableRange Rng, class Proj = identity,</pre>
```

```
IndirectCallablePredicate<Projected<IteratorType<Rng>, Proj>> Pred>
DifferenceType<IteratorType<Rng>>
    count_if(Rng&& rng, Pred pred, Proj proj = Proj{});

    Effects: Returns the number of iterators i in the range [first,last) for which the following corresponding conditions hold: *i == value, pred(*i) != false_INVOKE(proj, *i) == value, INVOKE(pred, INVOKE(proj, *i)) != false.

Complexity: Exactly last - first applications of the corresponding predicate and projection.
```

25.2.10 Mismatch [mismatch]

1

2

```
template<class InputIterator1, class InputIterator2>
 pair<InputIterator1, InputIterator2>
      mismatch(InputIterator1 first1, InputIterator1 last1,
               InputIterator2 first2);
template<class InputIterator1, class InputIterator2,</pre>
          class BinaryPredicate>
 pair<InputIterator1, InputIterator2>
      mismatch(InputIterator1 first1, InputIterator1 last1,
               InputIterator2 first2, BinaryPredicate pred);
template<class InputIterator1, class InputIterator2>
 pair<InputIterator1, InputIterator2>
    mismatch(InputIterator1 first1, InputIterator1 last1,
             InputIterator2 first2, InputIterator2 last2);
template<class InputIterator1, class InputIterator2,</pre>
           class BinaryPredicate>

      Projected<I2, Proj2>> Pred = equal_to<>>
 pair<IteratorType<Rng1>, I2>
    mismatch(Rng1& rng1, I2 first2, Pred pred = Pred{},
             Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
template<InputIterator I1, Sentinel<I1> S1, InputIterator I2, Sentinel<I2> S2,
    class Proj1 = identity, class Proj2 = identity,
    IndirectCallablePredicate<Projected<I1, Proj1>, Projected<I2, Proj2>> Pred = equal_to<>>
 pair<I1, I2>
    mismatch(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = Pred{},
             Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
```

```
template < Input Iterable Range Rng1, Input Iterable Range Rng2,
         class Proj1 = identity, class Proj2 = identity,
         IndirectCallablePredicate<Projected<IteratorType<Rng1>, Proj1>,
           Projected<IteratorType<Rng2>, Proj2>> Pred = equal_to<>>
       pair<IteratorType<Rng1>, IteratorType<Rng2>>
         mismatch(Rng1& rng1, Rng2& rng2, Pred pred = Pred{},
                  Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
  1
           Remarks: If last2 was not given in the argument list, it denotes first2 + (last1 - first1) below.
  2
           Returns: A pair of iterators i and j such that j == first2 + (i - first1) and i is the first iterator
          in the range [first1,last1) for which the following corresponding conditions hold:
(2.1)
            — j is in the range [first2, last2).
(2.2)
            - !(*i == *(first2 + (i - first1)))
(2.3)
            — pred(*i, *(first2 + (i - first1))) == false INVOKE (pred, INVOKE (proj1, *i), INVOKE (proj2,
               *(first2 + (i - first1)))) == false
          Returns the pair first1 + min(last1 - first1, last2 - first2) and first2 + min(last1 -
          first1, last2 - first2) if such an iterator i is not found.
  3
           Complexity: At most last1 - first1 applications of the corresponding predicate and both projections.
                                                                                              [alg.equal]
     25.2.11 Equal
     template<class InputIterator1, class InputIterator2>
       bool equal(InputIterator1 first1, InputIterator1 last1,
                  InputIterator2 first2);

 bool equal(I1 first1, S1 last1, I2 first2, S2 last2,
            Pred pred = Pred{},
            Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
template<Input IterableRange Rng1, Input IterableRange Rng2, class Pred = equal_to<>,
   class Proj1 = identity, class Proj2 = identity>
 requires IndirectlyComparable<IteratorType<Rng1>, IteratorType<Rng2>, Pred, Proj1, Proj2>
  bool equal(Rng1&& rng1, Rng2&& rng2, Pred pred = Pred{},
             Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
     Remarks: If last2 was not given in the argument list, it denotes first2 + (last1 - first1) below.
     Returns: If last1 - first1 != last2 - first2, return false. Otherwise return true if for every
     iterator i in the range [first1,last1) the following corresponding conditions holds: *i == *(first2
     + (i - first1)), pred(*i, *(first2 + (i - first1))) != false INVOKE (pred, INVOKE (proj1,
     *i), INVOKE (proj2, *(first2 + (i - first1)))) != false. Otherwise, returns false.
     Complexity: No applications of the corresponding predicate and projections if InputIterator1 and
     InputIterator2 meet the requirements of random access iterators I1 and S1 model SizedIteratorRange,
     and I2 and S2 model SizedIteratorRange, and last1 - first1 != last2 - first2. Otherwise,
     at most min(last1 - first1, last2 - first2) applications of the corresponding predicate and
     projections.
25.2.12
                                                                           [alg.is_permutation]
         Is permutation
```

template<class ForwardIterator1, class ForwardIterator2>

requires IndirectlyComparable<I1, I2, Pred, Proj1, Proj2>
bool is\_permutation(I1 first1, S1 last1, I2 first2,

Pred pred = Pred{},

1

3

1

2

3

4

```
Sentinel<I2> S2, class Pred = equal to<>, class Proj1 = identity,
    class Proj2 = identity>
  requires IndirectlyComparable<I1, I2, Pred, Proj1, Proj2>
 bool is_permutation(I1 first1, S1 last1, I2 first2, S2 last2,
                      Pred pred = Pred{},
                      Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
template<Forward Iterable Range Rng1, Forward Iterable Range Rng2, class Pred = equal_to<>,
    class Proj1 = identity, class Proj2 = identity>
  requires IndirectlyComparable<IteratorType<Rng1>, IteratorType<Rng2>, Pred, Proj1, Proj2>
  bool is_permutation(Rng1&& rng1, Rng2&& rng2, Pred pred = Pred{},
                      Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
     Requires: ForwardIterator1 and ForwardIterator2 shall have the same value type. The comparison
     function shall be an equivalence relation.
     Remarks: If last2 was not given in the argument list, it denotes first2 + (last1 - first1) below.
     Returns: If last1 - first1 != last2 - first2, return false. Otherwise return true if there
     exists a permutation of the elements in the range [first2,first2 + (last1 - first1)), beginning
     with ForwardIterator2 I2 begin, such that equal(first1, last1, begin, pred, proj1, proj2)
     returns true or equal(first1, last1, begin, pred) returns true; otherwise, returns false.
     Complexity: No applications of the corresponding predicate and projections if ForwardIterator1 and
     ForwardIterator2 meet the requirements of random access iterators I1 and S1 model SizedIteratorRange,
     and I2 and S2 model SizedIteratorRange, and last1 - first1 != last2 - first2. Other-
     wise, exactly distance(first1, last1) applications of the corresponding predicate and projections if
     equal(first1, last1, first2, last2, pred, proj1, proj2) would return true if pred was not
     given in the argument list or equal(first1, last1, first2, last2, pred) would return true if
     pred was given in the argument list; otherwise, at worst \mathcal{O}(N^2), where N has the value distance (first1,
     last1).
25.2.13 Search
                                                                                        [alg.search]
template < class ForwardIterator1, class ForwardIterator2>
 ForwardIterator1
    search(ForwardIterator1 first1, ForwardIterator1 last1,
           ForwardIterator2 first2, ForwardIterator2 last2);
template < class Forward Iterator 1, class Forward Iterator 2,
         class BinaryPredicate>
 ForwardIterator1
    search(ForwardIterator1 first1, ForwardIterator1 last1,
           ForwardIterator2 first2, ForwardIterator2 last2,
           BinaryPredicate pred);
template<ForwardIterator I1, Sentinel<I1> S1, ForwardIterator I2,
    Sentinel<I2> S2, class Pred = equal_to<>,
    class Proj1 = identity, class Proj2 = identity>
  requires IndirectlyComparable<I1, I2, Pred, Proj1, Proj2>
 I1
    search(I1 first1, S1 last1, I2 first2, S2 last2,
           Pred pred = Pred{},
           Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
template<Forward Iterable Range Rng1, Forward Iterable Range Rng2, class Pred = equal_to<>,
    class Proj1 = identity, class Proj2 = identity>
```

1

```
requires IndirectlyComparable<IteratorType<Rng1>, IteratorType<Rng2>, Pred, Proj1, Proj2>
    IteratorType<Rng1>
      search(Rng1& rng1, Rng2&& rng2, Pred pred = Pred{},
             Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
        Effects: Finds a subsequence of equal values in a sequence.
2
        Returns: The first iterator i in the range [first1,last1 - (last2-first2)) such that for every non-
       negative integer n less than last2 - first2 the following corresponding conditions holds: *(i + n)
       ==*(first2 + n), pred(*(i + n), *(first2 + n)) != false INVOKE (pred, INVOKE (proj1, *(i
        + n)), INVOKE (proj2, *(first2 + n))) != false. Returns first1 if [first2,last2) is empty,
       otherwise returns last1 if no such iterator is found.
3
        Complexity: At most (last1 - first1) * (last2 - first2) applications of the corresponding
       predicate and projections.
  template<class ForwardIterator, class Size, class T>
    ForwardIterator
      search_n(ForwardIterator first, ForwardIterator last, Size count,
             const T& value);
  template < class Forward Iterator, class Size, class T,
           class BinaryPredicate>
    ForwardIterator
      search_n(ForwardIterator first, ForwardIterator last, Size count,
             const T& value, BinaryPredicate pred);
  template<ForwardIterator I, Sentinel<I> S, class T,
      class Pred = equal_to<>, class Proj = identity>
    requires IndirectlyComparable<I1, const T*, Pred, Proj>
      search_n(I first, S last, DifferenceType<I> count,
               const T& value, Pred pred = Pred{},
               Proj proj = Proj{});
  template<ForwardIterableRange Rng, class T, class Pred = equal_to<>,
      class Proj = identity>
    requires IndirectlyComparable<IteratorType<Rng1>, const T*, Pred, Proj>
    IteratorType<Rng>
      search_n(Rng& rng, DifferenceType<IteratorType<Rng>> count,
               const T& value, Pred pred = Pred{}, Proj proj = Proj{});
4
        Requires: The type Size shall be convertible to integral type (4.7, 12.3).
5
        Effects: Finds a subsequence of equal values in a sequence.
6
        Returns: The first iterator i in the range [first,last-count) such that for every non-negative integer
       n less than count the following corresponding conditions holds: *(i + n) == value, pred(*(i +
       n), value) != false INVOKE (pred, INVOKE (proj, *(i + n)), value) != false. Returns last if
       no such iterator is found.
7
        Complexity: At most last - first applications of the corresponding predicate and projection.
                                                                         [alg.modifying.operations]
        Mutating sequence operations
                                                                                            [alg.copy]
  25.3.1 Copy
  template<class InputIterator, class OutputIterator>
    OutputIterator copy(InputIterator first, InputIterator last,
                        OutputIterator result);
```

```
template<InputIterator I, Sentinel<I> S, WeaklyIncrementable 0>
     requires IndirectlyCopyable<I, 0>
     pair<I, 0>
       copy(I first, S last, O result);
   template < Input Iterable Range Rng, Weakly Incrementable 0>
     requires IndirectlyCopyable<IteratorType<Rng>, 0>
     pair<IteratorType<Rng>, 0>
       copy(Rng& rng, 0 result);
1
         Effects: Copies elements in the range [first,last) into the range [result,result + (last -
        first)) starting from first and proceeding to last. For each non-negative integer n < (last -
        first), performs *(result + n) = *(first + n).
2
         Returns: result + (last - first) { last, result + (last - first) }.
3
         Requires: result shall not be in the range [first,last).
         Complexity: Exactly last - first assignments.
   template<class InputIterator, class Size, class OutputIterator>
     OutputIterator copy_n(InputIterator first, Size n,
                            OutputIterator result);
   template<WeakInputIterator I, WeaklyIncrementable 0>
     requires IndirectlyCopyable<I, 0>
     pair<I, 0>
       copy_n(I first, iterator_distance_t<I> n, 0 result);
5
         Effects: For each non-negative integer i < n, performs *(result + i) = *(first + i).
6
         Returns: result + n{first + n, result + n}.
7
         Complexity: Exactly n assignments.
   template < class InputIterator, class OutputIterator, class Predicate >
     OutputIterator copy_if(InputIterator first, InputIterator last,
                             OutputIterator result, Predicate pred);

     pair<IteratorType<Rng>, 0>
       copy_if(Rng& rng, O result, Pred pred, Proj proj = Proj{});
8
         Requires: The ranges [first,last) and [result,result + (last - first)) shall not overlap.
9
         Effects: Copies all of the elements referred to by the iterator i in the range [first,last) for which
        pred(*i) INVOKE(pred, INVOKE(proj, *i)) is true.
10
         Returns: The end of the resulting range {last, result + (last - first)}.
11
         Complexity: Exactly last - first applications of the corresponding predicate.
12
         Remarks: Stable (17.6.5.7).
```

```
template < class Bidirectional Iterator 1, class Bidirectional Iterator 2>
     BidirectionalIterator2
       copy_backward(BidirectionalIterator1 first,
                      BidirectionalIterator1 last,
                      BidirectionalIterator2 result);
   template<BidirectionalIterator I1, Sentinel<I1> S1, BidirectionalIterator I2>
     requires IndirectlyCopyable<I1, I2>
     pair<I1, I2>
       copy_backward(I1 first, I1 last, I2 result);
   template < Bidirectional Iterable Range Rng, Bidirectional Iterator I >
     requires IndirectlyCopyable<IteratorType<Rng>, I>
     pair<IteratorType<Rng>, I>
       copy_backward(Rng& rng, I result);
13
         Effects: Copies elements in the range [first,last) into the range [result - (last-first),result
         ) starting from last - 1 and proceeding to first. For each positive integer n <= (last - first),
         performs *(result - n) = *(last - n).
14
         Requires: result shall not be in the range (first, last].
15
         Returns: result - (last - first) { last, result - (last - first) }.
16
         Complexity: Exactly last - first assignments.
   25.3.2 Move
                                                                                               [alg.move]
   template<class InputIterator, class OutputIterator>
     OutputIterator move(InputIterator first, InputIterator last,
                          OutputIterator result);
   template<InputIterator I, Sentinel<I> S, WeaklyIncrementable 0>
     requires IndirectlyMovable<I, 0>
     pair<I, 0>
       move(I first, S last, O result);
   template<Input <a href="IterableRange">IterableRange</a> Rng, WeaklyIncrementable 0>
     requires IndirectlyMovable<IteratorType<Rng>, 0>
     pair<IteratorType<Rng>, 0>
       move(Rng& rng, 0 result);
1
         Effects: Moves elements in the range [first,last) into the range [result,result + (last -
         first)) starting from first and proceeding to last. For each non-negative integer n < (last-first),
         performs *(result + n) = std::move(*(first + n)).
2
         Returns: result + (last - first) { last, result + (last - first) }.
3
         Requires: result shall not be in the range [first,last).
4
         Complexity: Exactly last - first move assignments.
   template < class BidirectionalIterator1, class BidirectionalIterator2>
     BidirectionalIterator2
       move_backward(BidirectionalIterator1 first,
                      BidirectionalIterator1 last,
                      BidirectionalIterator2 result);
     3) copy_backward should be used instead of copy when last is in the range [result - (last - first), result).
```

<sup>§ 25.3.2</sup> 

```
template < Bidirectional Iterator I1, Sentinel < I1 > S1, Bidirectional Iterator I2 >
        requires IndirectlyMovable<I1, I2>
        pair<I1, I2>
            move_backward(I1 first, I1 last, I2 result);
    template < Bidirectional <a href="IterableRange">IterableRange</a> Rng, Bidirectional <a href=
        requires IndirectlyMovable<IteratorType<Rng>, I>
        pair<IteratorType<Rng>, I>
            move_backward(Rng& rng, I result);
5
               Effects: Moves elements in the range [first,last) into the range [result - (last-first),result
              ) starting from last - 1 and proceeding to first. For each positive integer n <= (last - first),
              performs *(result - n) = std::move(*(last - n)).
6
               Requires: result shall not be in the range (first, last].
7
               Returns: result - (last - first) { last, result - (last - first) }.
8
               Complexity: Exactly last - first assignments.
                                                                                                                                                                        [alg.swap]
    25.3.3 swap
    template<class ForwardIterator1, class ForwardIterator2>
        ForwardIterator2
            swap_ranges(ForwardIterator1 first1, ForwardIterator1 last1,
                                  ForwardIterator2 first2);
    template<ForwardIterator I1, Sentinel<I1> S1, ForwardIterator I2>
        requires IndirectlySwappable<I1, I2>
        pair<I1, I2>
            swap_ranges(I1 first1, S1 last1, I2 first2);
    template<ForwardIterableRange Rng, ForwardIterator I>
        requires IndirectlySwappable<IteratorType<Rng>, I>
        pair<IteratorType<Rng>, I>
            swap_ranges(Rng& rng1, I first2);
    template<ForwardIterator I1, Sentinel<I1> S1, ForwardIterator I2, Sentinel<I2> S2>
        requires IndirectlySwappable<I1, I2>
        pair<I1, I2>
            swap_ranges(I1 first1, S1 last1, I2 first2, S2 last2);
    template<Forward Iterable Range Rng1, Forward Iterable Range Rng2>
        requires IndirectlySwappable<IteratorType<Rng1>, IteratorType<Rng2>>
        pair<IteratorType<Rng1>, IteratorType<Rng2>>
            swap_ranges(Rng1& rng1, Rng2& rng2);
1
              Effects: For the first two overloads, let last2 be first2 + (last1 - first1). For each non-negative
              integer n < (last1 - first1) n < min(last1 - first1, last2 - first2) performs: swap(*(first1
              + n), *(first2 + n)).
2
              Requires: The two ranges [first1,last1) and [first2,first2 + (last1 - first1)) [first2,last2)
              shall not overlap. *(first1 + n) shall be swappable with (19.2.18) *(first2 + n).
3
              Returns: first2 + (last1 - first1) {first1 + n, first2 + n}, where n is min(last1 - first1,
              last2 - first2).
4
               Complexity: Exactly last1 - first1min(last1 - first1, last2 - first2) swaps.
        4) move_backward should be used instead of move when last is in the range [result - (last - first), result).
```

```
template < class Forward Iterator 1, class Forward Iterator 2>
  void iter_swap(ForwardIterator1 a, ForwardIterator2 b);
     Effects: swap(*a, *b).
     Requires: a and b shall be dereferenceable. *a shall be swappable with (19.2.18) *b.
25.3.4 Transform
                                                                                      [alg.transform]
template<class InputIterator, class OutputIterator,

template<InputIterator I1, Sentinel<I1> S1, InputIterator I2, Sentinel<I2> S2,
    class Proj1 = identity, class Proj2 = identity,
    IndirectCallable<Projected<I1, Proj1>, Projected<I2, Proj2>> F,
    WeakOutputIterator<IndirectCallableResultType<F, Projected<I1, Proj1>,
```

```
Projected<I2, Proj2>>> 0>
    tuple<I1, I2, O>
    transform(I1 first1, S1 last1, I2 first2, S2 last2, O result,
              F binary_op, Proj1 proj1 = Proj1{}, proj2 proj2 = Proj2{});
  template < Input Iterable Range Rng1, Input Iterable Range Rng2,
      class Proj1 = identity, class Proj2 = identity,
      IndirectCallable<Projected<IteratorType<Rng1>, Proj1>,
        Projected<IteratorType<Rng2>, Proj2>> F,
      WeakOutputIterator<IndirectCallableResultType<F,</pre>
        Projected<IteratorType<Rng1>, Proj1>, Projected<IteratorType<Rng2>, Proj2>>> 0>
    tuple<IteratorType<Rng1>, IteratorType<Rng2>, 0>
      transform(Rng1& rng1, Rng2& rng2, O result,
                F binary_op, Proj1 proj1 = Proj1{}, proj2 proj2 = Proj2{});
1
       For binary transforms that do not take last2, let last2 be first2 + (last1 - first1). Let N be
        (last1 - first1) for unary transforms, or min(last1 - first1, last2 - first2) for binary
       transforms.
2
        Effects: Assigns through every iterator i in the range [result, result + \frac{\text{(last1 - first1)}}{N}) a new
       corresponding value equal to op(*(first1 + (i - result))) INVOKE (op, INVOKE (proj, *(first1
       + (i - result)))) or binary_op(*(first1 + (i - result)), *(first2 + (i - result))) INVOKE (binary_op,
        INVOKE(proj1, *(first1 + (i - result))), INVOKE(proj2, *(first2 + (i - result)))).
3
        Requires: op and binary_op shall not invalidate iterators or subranges, or modify elements in the ranges
        [first1, last1 first1 + N], [first2, first2 + (last1 - first1)N], and [result, result + (last1 - first1)N]
       - first1)N].<sup>5</sup>
4
        Returns: result + (last1 - first1) make_pair(first1 + N, result + N) or make_tuple(first1
       + N, first2 + N, result + N).
5
        Complexity: Exactly last1 - first1N applications of op or binary_op.
6
        Remarks: result may be equal to first1 in case of unary transform, or to first1 or first2 in case
       of binary transform.
                                                                                          [alg.replace]
  25.3.5 Replace
  template<class ForwardIterator, class T>
    void replace(ForwardIterator first, ForwardIterator last,
                  const T% old_value, const T% new_value);
  template < class Forward Iterator, class Predicate, class T>
    void replace_if(ForwardIterator first, ForwardIterator last,
                    Predicate pred, const T& new_value);
  template<ForwardIterator I, Sentinel<I> S, class T1, Semiregular T2, class Proj = identity>
    requires Writable<I, T2> &&
      IndirectCallableRelation<equal_to<>, Projected<I, Proj>, const T1 *>
      replace(I first, S last, const T1& old_value, const T2& new_value, Proj proj = Proj{});
  template<Forward Iterable Range Rng, class T1, Semiregular T2, class Proj = identity>
    requires Writable<IteratorType<Rng>, T2> &&
      IndirectCallableRelation<equal_to<>, Projected<IteratorType<Rng>, Proj>, const T1 *>
    IteratorType<Rng>
```

§ 25.3.5

5) The use of fully closed ranges is intentional.

```
replace(Rng& rng, const T1& old_value, const T2& new_value);
  template<ForwardIterator I, Sentinel<I> S, Semiregular T, class Proj = identity,
      IndirectCallablePredicate<Projected<I, Proj>> Pred>
    requires Writable<I, T>
    Ι
      replace if(I first, S last, Pred pred, const T& new_value, Proj proj = Proj{});
  template<Forward <a href="IterableRange">IterableRange</a> Rng, Semiregular T, class Proj = identity,
      IndirectCallablePredicate<Projected<IteratorType<Rng>, Proj>> Pred>
    requires Writable<IteratorType<Rng>, T>
    IteratorType<Rng>
      replace_if(Rng& rng, Pred pred, const T& new_value, Proj proj = Proj{});
        Requires: The expression *first = new_value shall be valid.
2
        Effects: Substitutes elements referred by the iterator i in the range [first,last) with new_value,
        when the following corresponding conditions hold: *i == old value INVOKE (proj, *i) == old value,
        pred(*i) != falseINVOKE(pred, INVOKE(proj, *i)) != false.
3
        Returns: last.
4
        Complexity: Exactly last - first applications of the corresponding predicate and projection.
  template<class InputIterator, class OutputIterator, class T>
    OutputIterator
      replace_copy(InputIterator first, InputIterator last,
                   OutputIterator result,
                   const T& old_value, const T& new_value);
  template<class InputIterator, class OutputIterator, class Predicate, class T>
    OutputIterator
      replace_copy_if(InputIterator first, InputIterator last,
                       OutputIterator result,
                       Predicate pred, const T& new_value);
  template<InputIterator I, Sentinel<I> S, class T1, Semiregular T2, WeakOutputIterator<T2> O,
      class Proj = identity>
    requires IndirectlyCopyable<I, 0> &&
      IndirectCallableRelation<equal_to<>, Projected<I, Proj>, const T1 *>
    pair<I, 0>
      replace_copy(I first, S last, O result, const T1& old_value, const T2& new_value,
                   Proj proj = Proj{});
  template<InputIterableRange Rng, class T1, Semiregular T2, WeakOutputIterator<T2> 0,
      class Proj = identity>
    requires IndirectlyCopyable<IteratorType<Rng>, 0> &&
      IndirectCallableRelation<equal_to<>, Projected<IteratorType<Rng>, Proj>, const T1 *>
    pair<IteratorType<Rng>, 0>
      replace_copy(Rng& rng, O result, const T1& old_value, const T2& new_value,
                   Proj proj = Proj{});
  template<InputIterator I, Sentinel<I> S, Semiregular T, WeakOutputIterator<T> O,
      class Proj = identity, IndirectCallablePredicate<Projected<I, Proj>> Pred>
    requires IndirectlyCopyable<I, 0>
    pair<I, 0>
      replace_copy_if(I first, S last, O result, Pred pred, const T& new_value,
                      Proj proj = Proj{});
```

```
template<InputIterableRange Rng, Semiregular T, WeakOutputIterator<T> 0, class Proj = identity,
      IndirectCallablePredicate<Projected<IteratorType<Rng>, Proj>> Pred>
    requires IndirectlyCopyable<IteratorType<Rng>, 0>
    pair<IteratorType<Rng>, 0>
      replace_copy_if(Rng& rng, O result, Pred pred, const T& new_value,
                       Proj proj = Proj{});
5
        Requires: The results of the expressions *first and new_value shall be writable to the result output
        iterator. The ranges [first,last) and [result,result + (last - first)) shall not overlap.
6
        Effects: Assigns to every iterator i in the range [result, result + (last - first)) either new_-
        value or *(first + (i - result)) depending on whether the following corresponding conditions
        hold:
          *(first + (i - result)) == old_value
          pred(*(first + (i - result))) != false
          INVOKE(proj, *(first + (i - result))) == old_value
          INVOKE(pred, INVOKE(proj, *(first + (i - result)))) != false
7
        Returns: {last, result + (last - first)}.
8
        Complexity: Exactly last - first applications of the corresponding predicate and projection.
  25.3.6 Fill
                                                                                                [alg.fill]
  template<class ForwardIterator, class T>
    void fill(ForwardIterator first, ForwardIterator last, const T& value);
  template < class OutputIterator, class Size, class T>
    OutputIterator fill_n(OutputIterator first, Size n, const T& value);
  template<Semiregular T, OutputIterator<T> 0, Sentinel<0> S>
    O fill(O first, S last, const T& value);
  template<Semiregular T, OutputIterableRange<T> Rng>
    IteratorType<Rng>
      fill(Rng& rng, const T& value);
  template<Semiregular T, WeakOutputIterator<T> 0>
    0 fill_n(0 first, DifferenceType<0> n, const T& value);
        Requires: The expression value shall be writable to the output iterator. The type Size shall be
        convertible to an integral type (4.7, 12.3).
2
        Effects: The first algorithm fill assigns value through all the iterators in the range [first,last).
        The second algorithm fill_n assigns value through all the iterators in the range [first,first + n)
        if n is positive, otherwise it does nothing.
3
        Returns: fill returns last. fill_n returns first + n for non-negative values of n and first for
        negative values.
        Complexity: Exactly last - first, n, or 0 assignments, respectively.
                                                                                         [alg.generate]
  25.3.7 Generate
  template < class Forward Iterator, class Generator >
    void generate (ForwardIterator first, ForwardIterator last,
                   Generator gen);
  § 25.3.7
                                                                                                     128
```

```
template<class OutputIterator, class Size, class Generator>
  OutputIterator generate_n(OutputIterator first, Size n, Generator gen);
template<Function F, OutputIterator<ResultType<F>>> 0,
    Sentinel<0> S>
  O generate(O first, S last, F gen);
template<Function F, OutputIterableRange<ResultType<F>> Rng>
  IteratorType<Rng>
    generate(Rng& rng, F gen);
template<Function F, WeakOutputIterator<ResultType<F>> 0>
  O generate_n(O first, DistanceType<0> n, F gen);
     Effects: The first algorithm generate invokes the function object gen and assigns the return value of
     gen through all the iterators in the range [first,last). The second algorithm generate_n invokes
     the function object gen and assigns the return value of gen through all the iterators in the range
     [first, first + n) if n is positive, otherwise it does nothing.
     Requires: gen takes no arguments, Size shall be convertible to an integral type (4.7, 12.3).
     Returns: generate returns last. generate_n returns first + n for non-negative values of n and
     first for negative values.
     Complexity: Exactly last - first, n, or 0 invocations of gen and assignments, respectively.
25.3.8 Remove
                                                                                        [alg.remove]
template<ForwardIterator I, Sentinel<I> S, class T, class Proj = identity>

  requires Permutable<I>
 I remove_if(I first, S last, Pred pred, Proj proj = Proj{});
template<Forward Iterable Range Rng, class Proj = identity,
    IndirectCallablePredicate<Projected<IteratorType<Rng>, Proj>> Pred>
 requires Permutable<IteratorType<Rng>>
  IteratorType<Rng>
    remove_if(Rng& rng, Pred pred, Proj proj = Proj{});
     Requires: The type of *first shall satisfy the MoveAssignable requirements (Table 22).
     Effects: Eliminates all the elements referred to by iterator i in the range [first,last) for which
     the following corresponding conditions hold: *i == value INVOKE (proj, *i) == value, pred(*i)
     != false INVOKE (pred, INVOKE (proj, *i)) != false.
     Returns: The end of the resulting range.
```

1

2

3

4

2

3

*Remarks:* Stable (17.6.5.7).

```
5 Complexity: Exactly last - first applications of the corresponding predicate and projection.
```

Note: each element in the range [ret,last), where ret is the returned value, has a valid but unspecified state, because the algorithms can eliminate elements by moving from elements that were originally in that range.

```
template<class InputIterator, class OutputIterator, class T>

4

5

6

7

8

```
-1) INVOKE (proj, *i) == INVOKE (proj, *(i - 1)) or pred(*i, *(i - 1))!= false INVOKE (pred,
     INVOKE(proj, *i), INVOKE(proj, *(i - 1))) != false.
     Returns: \(\frac{1}{2}\)A pair consisting of last and the end of the resulting range.
     Complexity: For nonempty ranges, exactly last - first - 1 applications of the corresponding pred-
     icate and no more than twice as many applications of the projection.
25.3.10 Reverse
                                                                                        [alg.reverse]
template < class BidirectionalIterator>
  void reverse(BidirectionalIterator first, BidirectionalIterator last);
template<BidirectionalIterator I, Sentinel<I> S>
  requires Permutable<I>
 I reverse(I first, S last);
template < Bidirectional Iterable Range Rng>
  requires Permutable<IteratorType<Rng>>
  IteratorType<Rng>
    reverse(Rng& rng);
     Effects: For each non-negative integer i < (last - first)/2, applies iter_swap to all pairs of iter-
     ators first + i, (last - i) - 1.
     Requires: *first shall be swappable (19.2.18).
     Returns: last.
     Complexity: Exactly (last - first)/2 swaps.
template<class BidirectionalIterator, class OutputIterator>
  OutputIterator
    reverse_copy(BidirectionalIterator first,
                 BidirectionalIterator last, OutputIterator result);
template<BidirectionalIterator I, Sentinel<I> S, WeaklyIncrementable O>
  requires IndirectlyCopyable<I, 0>
 pair<I, 0> reverse_copy(I first, S last, 0 result);
template < Bidirectional <a href="Iterable-Range">Iterable-Range</a> Rng, Weakly Incrementable 0>
  requires IndirectlyCopyable<IteratorType<Rng>, 0>
 pair<IteratorType<Rng>, 0>
    reverse_copy(Rng& rng, 0 result);
     Effects: Copies the range [first,last) to the range [result,result+(last-first)) such that for
     every non-negative integer i < (last - first) the following assignment takes place: *(result +
     (last - first) - 1 - i) = *(first + i).
     Requires: The ranges [first,last) and [result,result+(last-first)) shall not overlap.
     Returns: result + (last - first) { last, result + (last - first) }.
     Complexity: Exactly last - first assignments.
25.3.11 Rotate
                                                                                         [alg.rotate]
template<class ForwardIterator>
 ForwardIterator rotate(ForwardIterator first, ForwardIterator middle,
              ForwardIterator last);
```

```
template<ForwardIterator I, Sentinel<I> S>
    requires Permutable<I>
    pair<I, I> rotate(I first, I middle, S last);
  template<ForwardIterableRange Rng>
    requires Permutable<IteratorType<Rng>>
    pair<IteratorType<Rng>, IteratorType<Rng>>
      rotate(Rng& rng, IteratorType<Rng> middle);
1
        Effects: For each non-negative integer i < (last - first), places the element from the position
       first + i into position first + (i + (last - middle)) % (last - first).
        Returns: first + (last - middle) {first + (last - middle), last}.
3
        Remarks: This is a left rotate.
        Requires: [first,middle) and [middle,last) shall be valid ranges. ForwardIterator shall satisfy
       the requirements of ValueSwappable (19.2.18). The type of *first shall satisfy the requirements of
       MoveConstructible (Table 20) and the requirements of MoveAssignable (Table 22).
5
        Complexity: At most last - first swaps.
  template<class ForwardIterator, class OutputIterator>
    OutputIterator
      rotate_copy(ForwardIterator first, ForwardIterator middle,
                  ForwardIterator last, OutputIterator result);
  template<ForwardIterator I, Sentinel<I> S, WeaklyIncrementable 0>
    requires IndirectlyCopyable<I, 0>
    pair<I, 0>
      rotate_copy(I first, I middle, S last, O result);
  template<Forward Iterable Range Rng, Weakly Incrementable 0>
    requires IndirectlyCopyable<IteratorType<Rng>, 0>
    pair<IteratorType<Rng>, 0>
      rotate_copy(Rng& rng, IteratorType<Rng> middle, 0 result);
6
        Effects: Copies the range [first,last) to the range [result,result + (last - first)) such that
       for each non-negative integer i < (last - first) the following assignment takes place: *(result +
       i) = *(first + (i + (middle - first)) % (last - first)).
7
        Returns: result + (last - first) {last, result + (last - first)}.
8
        Requires: The ranges [first,last) and [result,result + (last - first)) shall not overlap.
9
        Complexity: Exactly last - first assignments.
  25.3.12 Shuffle
                                                                                [alg.random.shuffle]
  template < class Random AccessIterator, class Uniform Random Number Generator >
    void shuffle(RandomAccessIterator first,
                        RandomAccessIterator last,
                        UniformRandomNumberGenerator&& g);
  template<RandomAccessIterator I, Sentinel<I> S, UniformRandomNumberGeneratorclass Gen>
    requires Permutable<I> && Convertible<ResultType<Gen>, DifferenceType<I>> &&
      UniformRandomNumberGenerator<remove_reference_t<Gen>>
    I shuffle(I first, S last, Gen&& g);
  template<RandomAccessIterableRange Rng, UniformRandomNumberGeneratorclass Gen>
```

1

2

3

4

5

2

3

that do not satisfy it.

```
requires Permutable<I> && Convertible<ResultType<Gen>, DifferenceType<I>> &&
    UniformRandomNumberGenerator<remove_reference_t<Gen>>
  IteratorType<Rng>
    shuffle(Rng& rng, Gen&& g);
     Effects: Permutes the elements in the range [first,last) such that each possible permutation of
     those elements has equal probability of appearance.
     Requires: RandomAccessIterator shall satisfy the requirements of ValueSwappable (19.2.18). The
     type UniformRandomNumberGenerator shall meet the requirements of a uniform random number gen-
     erator (26.5.1.3) type whose return type is convertible to iterator_traits<RandomAccessItera-
     tor>::difference_type.
     Complexity: Exactly (last - first) - 1 swaps.
     Returns: last
     Remarks: To the extent that the implementation of this function makes use of random numbers, the
     object g shall serve as the implementation's source of randomness.
25.3.13 Partitions
                                                                                     [alg.partitions]
template < class InputIterator, class Predicate >
 bool is_partitioned(InputIterator first, InputIterator last, Predicate pred);
template<InputIterator I, Sentinel<I> S, class Proj = identity,
    IndirectCallablePredicate<Projected<I, Proj>> Pred>
 bool is_partitioned(I first, S last, Pred pred, Proj proj = Proj{});
template<Input\frac{IterableRange}{} Rng, class Proj = identity,</pre>
    IndirectCallablePredicate<Projected<IteratorType<Rng>, Proj>> Pred>
 bool
    is_partitioned(Rng&& rng, Pred pred, Proj proj = Proj{});
     Requires: InputIterator's value type shall be convertible to Predicate's argument type.
     Returns: true if [first,last) is empty or if [first,last) is partitioned by pred and proj, i.e. if all
     elements that satisfy pred appear iterators i for which INVOKE (pred, INVOKE (proj, *i)) != false
     come before those that do not, for every i in [first,last).
     Complexity: Linear. At most last - first applications of pred and proj.
template < class Forward Iterator, class Predicate >
 ForwardIterator
    partition(ForwardIterator first,
              ForwardIterator last, Predicate pred);
template<ForwardIterator I, Sentinel<I> S, class Proj = identity,
    IndirectCallablePredicate<Projected<I, Proj>> Pred>
 requires Permutable<I>
  I partition(I first, S last, Pred pred, Proj proj = Proj{});
template<ForwardIterableRange Rng, class Proj = identity,</pre>
    IndirectCallablePredicate<Projected<IteratorType<Rng>, Proj>> Pred>
  requires Permutable<IteratorType<Rng>>
  IteratorType<Rng>
    partition(Rng& rng, Pred pred, Proj proj = Proj{});
      Effects: Places all the elements in the range [first,last) that satisfy pred before all the elements
```

Effects: Permutes the elements in the range [first,last) such that there exists and iterator i such that for every iterator j in the range [first,i) INVOKE (pred, INVOKE (proj, \*j)) != false, and

```
for every iterator k in the range [i,last), INVOKE (pred, INVOKE (proj, *k)) == false
5
         Returns: An iterator i such that for every iterator j in the range [first,i) pred(*j) != false INVOKE (pred,
         INVOKE (proj, *j)) != false, and for every iterator k in the range [i,last), pred(*k) == false INVOKE (pred,
         INVOKE(proj, *k)) == false.
6
         Requires: ForwardIterator shall satisfy the requirements of ValueSwappable (19.2.18).
7
         Complexity: If ForwardIterator meets the requirements for a BidirectionalIterator, at most (last -
         first) / 2 swaps are done; otherwise at most last - first swaps are done. Exactly last - first
         applications of the predicate and projection are done.
   template<class BidirectionalIterator, class Predicate>
     BidirectionalIterator
       stable_partition(BidirectionalIterator first,
                         BidirectionalIterator last, Predicate pred);
   template<BidirectionalIterator I, Sentinel<I> S, class Proj = identity,
       IndirectCallablePredicate<Projected<I, Proj>> Pred>
     requires Permutable<I>
     I stable_partition(I first, S last, Pred pred, Proj proj = Proj{});
   template < Bidirectional <a href="IterableRange">IterableRange</a> Rng, class Proj = identity,

     requires Permutable<IteratorType<Rng>>
     IteratorType<Rng>
       stable_partition(Rng& rng, Pred pred, Proj proj = Proj{});
8
         Effects: Places all the elements in the range [first,last) that satisfy pred before all the elements
         that do not satisfy it.
         Effects: Permutes the elements in the range [first,last) such that there exists and iterator i such
         that for every iterator j in the range [first,i) INVOKE (pred, INVOKE (proj, *j)) != false, and
         for every iterator k in the range [i,last), INVOKE (pred, INVOKE (proj, *k)) == false
9
         Returns: An iterator i such that for every iterator j in the range [first,i), pred(*j) != false INVOKE (pred,
         INVOKE (proj, *j)) != false, and for every iterator k in the range [i,last), pred(*k) == false INVOKE (pred,
         INVOKE (proj, *k)) == false. The relative order of the elements in both groups is preserved.
10
         Requires: BidirectionalIterator shall satisfy the requirements of ValueSwappable (19.2.18). The
         type of *first shall satisfy the requirements of MoveConstructible (Table 20) and of MoveAssignable
11
         Complexity: At most (last - first) * log(last - first) swaps, but only linear number of swaps
         if there is enough extra memory. Exactly last - first applications of the predicate and projection.
   template < class InputIterator, class OutputIterator1,
              class OutputIterator2, class Predicate>
     pair<OutputIterator1, OutputIterator2>

    IndirectCallablePredicate<Projected<IteratorType<Rng>, Proj>> Pred>
    IteratorType<Rng>
    partition_point(Rng& rng, Pred pred, Proj proj = Proj{});
```

Requires: ForwardIterator's value type shall be convertible to Predicate's argument type. [first, last) shall be partitioned by pred and proj, i.e. all elements that satisfy pred shall appear before those that do not there should be an iterator mid such that all\_of(first, mid, pred, proj) and none\_of(mid, last, pred, proj) are both true.

- Returns: An iterator mid such that all\_of(first, mid, pred, proj) and none\_of(mid, last, pred, proj) are both true.
- Complexity:  $\mathcal{O}(log(last first))$  applications of pred and proj.

## 25.4 Sorting and related operations

[alg.sorting]

- All the operations in 25.4 have two versions: one that takes a function object of type Compare and one that uses an operator take an optional binary callable predicate of type Comp that defaults to less<>.
- <sup>2</sup> CompareComp is a function object type (20.9)an callable object (20.9.2). The return value of the function call operation the *INVOKE* operation applied to an object of type CompareComp, when contextually converted to bool (Clause 4), yields true if the first argument of the call is less than the second, and false otherwise. CompareComp comp is used throughout for algorithms assuming an ordering relation. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.
- <sup>3</sup> For all algorithms that take Compare, there is a version that uses operator<instead. That is, comp(\*i, \*j) != false defaults to \*i < \*j != false. For algorithms other than those described in 25.4.3 to work correctly, comp has to induce a strict weak ordering on the values.
  - [Editor's note: REVIEW: The above (struck) sentence implies that the binary search algorithms do not require a strict weak ordering relation, but the "Palo Alto report" is clear that they do. Which is it?]
  - [Editor's note: The following description of "strict weak order" has moved to the definition of the StrictWeakOrder concept (19.4.6).]
- 4 The term *strict* refers to the requirement of an irreflexive relation (!comp(x, x)! INVOKE(comp, x, x) for all x), and the term *weak* to requirements that are not as strong as those for a total ordering, but stronger than those for a partial ordering. If we define equiv(a, b) as !comp(a, b) && !comp(b, a)! INVOKE(comp, a, b) && !INVOKE(comp, b, a), then the requirements are that comp and equiv both be transitive relations:
- (4.1) comp(a, b) && comp(b, c) INVOKE (comp, a, b) && INVOKE (comp, b, c) implies comp(a, c) INVOKE (comp, a, c)
- equiv(a, b) && equiv(b, c) implies equiv(a, c) [Note: Under these conditions, it can be shown that
- (4.2.1) equiv is an equivalence relation
- (4.2.2) comp induces a well-defined relation on the equivalence classes determined by equiv
- (4.2.3) The induced relation is a strict total ordering. end note
  - A sequence is sorted with respect to a comparator and projection comp and proj if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, comp(\*(i + n), \*i) == false INVOKE(comp, INVOKE(proj, \*(i + n)), INVOKE(proj, \*i)) == false.

<sup>6</sup> A sequence [start,finish) is partitioned with respect to an expression f(e) if there exists an integer n such that for all 0 <= i < distance(start, finish), f(\*(start + i)) is true if and only if i < n.

7 In the descriptions of the functions that deal with ordering relationships we frequently use a notion of equivalence to describe concepts such as stability. The equivalence to which we refer is not necessarily an operator==, but an equivalence relation induced by the strict weak ordering. That is, two elements a and b are considered equivalent if and only if !(a < b) && !(b < a).

```
25.4.1 Sorting
                                                                                            [alg.sort]
25.4.1.1 sort
                                                                                                 [sort]
template < class Random Access Iterator >
  void sort(RandomAccessIterator first, RandomAccessIterator last);
template < class Random Access Iterator, class Compare >
  void sort(RandomAccessIterator first, RandomAccessIterator last,
            Compare comp);
template<RandomAccessIterator I, Sentinel<I> S, class Comp = less<>,
    class Proj = identity>
  requires Sortable<I, Comp, Proj>
  I sort(I first, S last, Comp comp = Comp{}, Proj proj = Proj{});
template<RandomAccessIterableRange Rng, class Comp = less<>, class Proj = identity>
  requires Sortable<IteratorType<Rng>, Comp, Proj>
  IteratorType<Rng>
    sort(Rng& rng, Comp comp = Comp{}, Proj proj = Proj{});
     Effects: Sorts the elements in the range [first,last).
     Requires: RandomAccessIterator shall satisfy the requirements of ValueSwappable (19.2.18). The
     type of *first shall satisfy the requirements of MoveConstructible (Table 20) and of MoveAssignable
     (Table 22).
     Complexity: \mathcal{O}(N \log(N)) (where N == last - first) comparisons.
25.4.1.2 stable sort
                                                                                          [stable.sort]
template < class Random Access Iterator >
  void stable_sort(RandomAccessIterator first, RandomAccessIterator last);
template < class Random Access Iterator, class Compare >
  void stable_sort(RandomAccessIterator first, RandomAccessIterator last,
                   Compare comp);
template<RandomAccessIterator I, Sentinel<I> S, class Comp = less<>,
    class Proj = identity>
  requires Sortable<I, Comp, Proj>
  I stable_sort(I first, S last, Comp comp = Comp{}, Proj proj = Proj{});
template<RandomAccessIterableRange Rng, class Comp = less<>, class Proj = identity>
 requires Sortable < Iterator Type < Rng > , Comp, Proj >
 IteratorType<Rng>
    stable_sort(Rng& rng, Comp comp = Comp{}, Proj proj = Proj{});
     Effects: Sorts the elements in the range [first,last).
```

1

2

3

§ 25.4.1.2

```
Requires: RandomAccessIterator shall satisfy the requirements of ValueSwappable (19.2.18). The type of *first shall satisfy the requirements of MoveConstructible (Table 20) and of MoveAssignable (Table 22).
```

- Complexity: It does at most  $N \log^2(N)$  (where N == last first) comparisons; if enough extra memory is available, it is  $N \log(N)$ .
- 4 Remarks: Stable (17.6.5.7).

```
25.4.1.3 partial_sort
```

[partial.sort]

```
template < class Random Access Iterator >
  void partial_sort(RandomAccessIterator first,
                    RandomAccessIterator middle,
                    RandomAccessIterator last);
template<class RandomAccessIterator, class Compare>
  void partial_sort(RandomAccessIterator first,
                    RandomAccessIterator middle,
                    RandomAccessIterator last,
                    Compare comp);
template<RandomAccessIterator I, Sentinel<I> S, class Comp = less<>,
    class Proj = identity>
  requires Sortable<I, Comp, Proj>
  I partial_sort(I first, I middle, S last, Comp comp = Comp{}, Proj proj = Proj{});
template<RandomAccessIterableRange Rng, class Comp = less<>, class Proj = identity>
  requires Sortable<IteratorType<Rng>, Comp, Proj>
  IteratorType<Rng>
    partial_sort(Rng& rng, IteratorType<Rng> middle, Comp comp = Comp{},
                 Proj proj = Proj{});
```

- Effects: Places the first middle first sorted elements from the range [first,last) into the range [first,middle). The rest of the elements in the range [middle,last) are placed in an unspecified order.
- Requires: RandomAccessIterator shall satisfy the requirements of ValueSwappable (19.2.18). The type of \*first shall satisfy the requirements of MoveConstructible (Table 20) and of MoveAssignable (Table 22).
- 3 Complexity: It takes approximately (last first) \* log(middle first) comparisons.

## 25.4.1.4 partial\_sort\_copy

1

[partial.sort.copy]

§ 25.4.1.4

```
template<InputIterator I1, Sentinel<I> S1, RandomAccessIterator I2, Sentinel<I> S2,
      class R = less<>, class Proj = identity>
    requires IndirectlyCopyable<I1, I2> && Sortable<I2, Comp, Proj>
    T2
      partial_sort_copy(I1 first, S1 last, I2 result_first, S2 result_last,
                        Comp comp = Comp{}, Proj proj = Proj{});
  template<InputIterableRange Rng1, RandomAccessIterableRange Rng2, class R = less<>,
      class Proj = identity>
    requires IndirectlyCopyable<IteratorType<Rng1>, IteratorType<Rng2>> &&
        Sortable<IteratorType<Rng2>, Comp, Proj>
    IteratorType<Rng2>
      partial_sort_copy(Rng1& rng, Rng2& result_rng, Comp comp = Comp{},
                        Proj proj = Proj{});
1
        Effects: Places the first min(last - first, result_last - result_first) sorted elements into the
       range [result_first,result_first + min(last - first, result_last - result_first)).
2
        Returns: The smaller of: result_last or result_first + (last - first).
        Requires: RandomAccessIterator shall satisfy the requirements of ValueSwappable (19.2.18). The
       type of *result_first shall satisfy the requirements of MoveConstructible (Table 20) and of Move-
       Assignable (Table 22).
4
        Complexity: Approximately (last - first) * log(min(last - first, result_last - result_-
       first)) comparisons.
  25.4.1.5 is_sorted
                                                                                            [is.sorted]
  template<class ForwardIterator>
    bool is_sorted(ForwardIterator first, ForwardIterator last);
  template<ForwardIterator I, Sentinel<I> S, class Proj = identity,
      IndirectCallableRelationStrictWeakOrder<Projected<I, Proj>> Comp = less<>>
    bool is_sorted(I first, S last, Comp comp = Comp{}, Proj proj = Proj{});
  template<Forward Iterable Range Rng, class Proj = identity,
      IndirectCallableRelationStrictWeakOrder<Projected<IteratorType<Rng>, Proj>> Comp = less<>>
    bool
      is_sorted(Rng&& rng, Comp comp = Comp{}, Proj proj = Proj{});
        Returns: is_sorted_until(first, last, comp, proj) == last
  template<class ForwardIterator, class Compare>
    bool is_sorted(ForwardIterator first, ForwardIterator last,
      Compare comp);
        Returns: is_sorted_until(first, last, comp) == last
  template < class ForwardIterator>
    ForwardIterator is_sorted_until(ForwardIterator first, ForwardIterator last);
  template<class ForwardIterator, class Compare>
    ForwardIterator is_sorted_until(ForwardIterator first, ForwardIterator last,
      Compare comp);
  template<ForwardIterator I, Sentinel<I> S, class Proj = identity,
      IndirectCallableRelationStrictWeakOrder<Projected<I, Proj>> Comp = less<>>
    I is_sorted_until(I first, S last, Comp comp = Comp{}, Proj proj = Proj{});
```

§ 25.4.1.5

```
template<ForwardIterableRange Rng, class Proj = identity,
    IndirectCallableRelationStrictWeakOrder
Projected<IteratorType<Rng>, Proj>> Comp = less<>>
    IteratorType<Rng>
    is_sorted_until(Rng& rng, Comp comp = Comp{}, Proj proj = Proj{});
```

Returns: If distance(first, last) < 2, returns last. Otherwise, returns the last iterator i in [first,last] for which the range [first,i) is sorted.

4 Complexity: Linear.

#### 25.4.2 Nth element

[alg.nth.element]

- After nth\_element the element in the position pointed to by nth is the element that would be in that position if the whole range were sorted, unless nth == last. Also for every iterator i in the range [first,nth) and every iterator j in the range [nth,last) it holds that: !(\*j < \*i) or comp(\*j, \*i) == false INVOKE(comp, INVOKE(proj, \*j), INVOKE(proj, \*i)) == false.
- Requires: RandomAccessIterator shall satisfy the requirements of ValueSwappable (19.2.18). The type of \*first shall satisfy the requirements of MoveConstructible (Table 20) and of MoveAssignable (Table 22).
- 3 Complexity: Linear on average.

#### 25.4.3 Binary search

1

[alg.binary.search]

All of the algorithms in this section are versions of binary search and assume that the sequence being searched is partitioned with respect to an expression formed by binding the search key to an argument of the implied or explicit comparison function and projection. They work on non-random access iterators minimizing the number of comparisons, which will be logarithmic for all types of iterators. They are especially appropriate for random access iterators, because these algorithms do a logarithmic number of steps through the data structure. For non-random access iterators they execute a linear number of steps.

#### 25.4.3.1 lower\_bound

[lower.bound]

§ 25.4.3.1

```
ForwardIterator
      lower_bound(ForwardIterator first, ForwardIterator last,
                  const T& value, Compare comp);
  template<ForwardIterator I, Sentinel<I> S, TotallyOrdered T, class Proj = identity,
      IndirectCallableRelationStrictWeakOrder<const T *, Projected<I, Proj>> Comp = less<>>
      lower_bound(I first, S last, const T& value, Comp comp = Comp{},
                   Proj proj = Proj{});
  template<Forward Iterable Range Rng, Totally Ordered T, class Proj = identity,
      IndirectCallableRelationStrictWeakOrder<const T *, Projected<IteratorType<Rng>, Proj>> Comp = less<>>
    IteratorType<Rng>
      lower_bound(Rng& rng, const T& value, Comp comp = Comp{}, Proj proj = Proj{});
        Requires: The elements e of [first,last) shall be partitioned with respect to the expression e-<
1
        value INVOKE (comp, INVOKE (proj, e), value) or comp(e, value).
2
        Returns: The furthermost iterator i in the range [first,last] such that for every iterator j in the
        range [first,i) the following corresponding conditions hold: *j < value or comp(*j, value) !=
        false INVOKE (comp, INVOKE (proj, *j), value) != false.
3
        Complexity: At most \log_2(\text{last - first}) + \mathcal{O}(1) comparisons applications of the comparison function
        and projection.
  25.4.3.2 upper_bound
                                                                                          [upper.bound]
  template<class ForwardIterator, class T>
    ForwardIterator
      upper_bound(ForwardIterator first, ForwardIterator last,
                  const T& value);
  template < class ForwardIterator, class T, class Compare >
    ForwardIterator
      upper_bound(ForwardIterator first, ForwardIterator last,
                   const T& value, Compare comp);
  template<ForwardIterator I, Sentinel<I> S, TotallyOrdered T, class Proj = identity,
      IndirectCallableRelationStrictWeakOrder<const T *, Projected<I, Proj>> Comp = less<>>
      upper_bound(I first, S last, const T& value, Comp comp = Comp{}, Proj proj = Proj{});
  template<Forward Iterable Range Rng, Totally Ordered T, class Proj = identity,
      IndirectCallableRelationStrictWeakOrder<const T *, Projected<IteratorType<Rng>, Proj>> Comp = less<>>
    IteratorType<Rng>
      upper_bound(Rng& rng, const T& value, Comp comp = Comp{}, Proj proj = Proj{});
        Requires: The elements e of [first,last) shall be partitioned with respect to the expression !(value

< e)! INVOKE (comp, value, INVOKE (proj, e)) or !comp(value, e).
</pre>
        Returns: The furthermost iterator i in the range [first,last] such that for every iterator j in the
        range [first,i) the following corresponding conditions hold: !(value < *j) or comp(value, *j)
        == false INVOKE (comp, value, INVOKE (proj, *j)) == false.
3
        Complexity: At most \log_2(\text{last - first}) + \mathcal{O}(1) comparisons applications of the comparison function
        and projection.
  25.4.3.3
             equal_range
                                                                                           [equal.range]
```

§ 25.4.3.3

```
template<class ForwardIterator, class T>
    pair<ForwardIterator, ForwardIterator>
      equal_range(ForwardIterator first,
                   ForwardIterator last, const T& value);
  template < class ForwardIterator, class T, class Compare >
    pair<ForwardIterator, ForwardIterator>
      equal_range(ForwardIterator first,
                   ForwardIterator last, const T& value,
                   Compare comp);
  template<ForwardIterator I, Sentinel<I> S, TotallyOrdered T, class Proj = identity,
      IndirectCallableRelationStrictWeakOrder<const T *, Projected<I, Proj>> Comp = less<>>
    pair<I, I>
      equal_range(I first, S last, const T& value, Comp comp = Comp{}, Proj proj = Proj{});
  template<Forward Iterable Range Rng, Totally Ordered T, class Proj = identity,
       IndirectCallable<del>Relation</del>StrictWeakOrder<const T *, Projected<IteratorType<Rng>, Proj>> Comp = less<>>
    pair<IteratorType<Rng>, IteratorType<Rng>>
      equal_range(Rng& rng, const T& value, Comp comp = Comp{}, Proj proj = Proj{});
1
        Requires: The elements e of [first,last) shall be partitioned with respect to the expressions e
        value INVOKE (comp, INVOKE (proj, e), value) and !(value < e)! INVOKE (comp, value, INVOKE (proj,</pre>
        e)) or comp(e, value) and !comp(value, e). Also, for all elements e of [first, last), e <
        value INVOKE (comp, INVOKE (proj, e), value) shall imply !(value < e)! INVOKE (comp, value,</pre>
        INVOKE (proj, e)) or comp(e, value) shall imply !comp(value, e).
2
        Returns:
          make_pair(lower_bound(first, last, value),
                    upper_bound(first, last, value))
        or
          make_pair(lower_bound(first, last, value, comp, proj),
                    upper_bound(first, last, value, comp, proj))
        Complexity: At most 2*\log_2(\text{last} - \text{first}) + \mathcal{O}(1) comparisons applications of the comparison function
        and projection.
  25.4.3.4 binary_search
                                                                                         [binary.search]
  template<class ForwardIterator, class T>
    bool binary_search(ForwardIterator first, ForwardIterator last,
                        const T& value);
  template<class ForwardIterator, class T, class Compare>
    bool binary_search(ForwardIterator first, ForwardIterator last,
                        const T& value, Compare comp);
  template<ForwardIterator I, Sentinel<I> S, TotallyOrdered T, class Proj = identity,
      IndirectCallableRelationStrictWeakOrder<const T *, Projected<I, Proj>> Comp = less<>>
    bool
      binary_search(I first, S last, const T& value, Comp comp = Comp{},
                     Proj proj = Proj{});
  template<Forward Iterable Range Rng, Totally Ordered T, class Proj = identity,
      IndirectCallableRelationStrictWeakOrder<const T *, Projected<IteratorType<Rng>, Proj>> Comp = less<>>
  § 25.4.3.4
                                                                                                      143
```

bool

```
binary_search(Rng& rng, const T& value, Comp comp = Comp{},
                    Proj proj = Proj{});
1
       Requires: The elements e of [first,last) are partitioned with respect to the expressions
       value INVOKE (comp, INVOKE (proj, e), value) and !(value ← e)! INVOKE (comp, value, INVOKE (proj,
       e)) or comp(e, value) and !comp(value, e). Also, for all elements e of [first, last), e <
       value INVOKE (comp, INVOKE (proj, e), value) shall imply !(value < e)! INVOKE (comp, value,</pre>
        INVOKE (proj, e)) or comp(e, value) shall imply !comp(value, e).
2
        Returns: true if there is an iterator i in the range [first,last) that satisfies the corresponding con-
       ditions: !(*i < value) && !(value < *i) INVOKE(comp, INVOKE(proj, *i), value) == false
       && INVOKE (comp, value, INVOKE (proj, *i)) == false or comp(*i, value) == false && comp(value,
       *i) == false.
3
        Complexity: At most \log_2(\text{last - first}) + \mathcal{O}(1) comparisons applications of the comparison function
       and projection.
                                                                                          [alg.merge]
  25.4.4 Merge
  template<class InputIterator1, class InputIterator2,</pre>
           class OutputIterator>
    OutputIterator
      merge(InputIterator1 first1, InputIterator1 last1,
            InputIterator2 first2, InputIterator2 last2,
            OutputIterator result);
  template<class InputIterator1, class InputIterator2,</pre>
           class OutputIterator, class Compare>
    OutputIterator
      merge(InputIterator1 first1, InputIterator1 last1,
            InputIterator2 first2, InputIterator2 last2,
            OutputIterator result, Compare comp);
  template<InputIterator I1, Sentinel<I1> S1, InputIterator I2, Sentinel<I2> S2,
      Incrementable O, class Comp = less<>, class Proj1 = identity,
      class Proj2 = identity>
    requires Mergeable<I1, I2, O, Comp, Proj1, Proj2>
    tuple<I1, I2, 0>
      merge(I1 first1, S1 last1, I2 first2, S2 last2, O result,
            Comp comp = Comp{}, Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
  template<InputIterableRange Rng1, InputIterableRange Rng2, Incrementable O, class Comp = less<>,
      class Proj1 = identity, class Proj2 = identity>
    requires Mergeable<IteratorType<Rng1>, IteratorType<Rng2>, O, Comp, Proj1, Proj2>
    tuple<IteratorType<Rng1>, IteratorType<Rng2>, 0>
      merge(Rng1& rng1, Rng2& rng2, O result,
            Comp comp = Comp{}, Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
1
        Effects: Copies all the elements of the two ranges [first1,last1) and [first2,last2) into the range
        [result_result_last), where result_last is result + (last1 - first1) + (last2 - first2),
       such that the resulting range satisfies is_sorted(result, result_last) or [Editor's note: TODO
       The following postcondition isn't well-formed: is_sorted(result, result_last, comp), respectively.
2
        Requires: The ranges [first1,last1) and [first2,last2) shall be sorted with respect to operator
       or comp, proj1, and proj2. The resulting range shall not overlap with either of the original ranges.
```

§ 25.4.4

3

```
Returns: result + (last1 - first1) + (last2 - first2) make_tuple(last1, last2, result
        + (last1 - first1) + (last2 - first2)).
4
        Complexity: At most (last1 - first1) + (last2 - first2) - 1 comparisons applications of the
        comparison function and each projection.
5
        Remarks: Stable (17.6.5.7).
   template < Input Iterator I1, Sentinel < I1 > S1, Input Iterator I2, Sentinel < I2 > S2,
       Incrementable O, class Comp = less<>, class Proj1 = identity,
       class Proj2 = identity>
     requires MergeMovable<I1, I2, O, Comp, Proj1, Proj2>
     tuple<I1, I2, 0>
       merge_move(I1 first1, S1 last1, I2 first2, S2 last2, O result,
             Comp comp = Comp{}, Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
   template<InputIterableRange Rng1, InputIterableRange Rng2, Incrementable O, class Comp = less<>,
       class Proj1 = identity, class Proj2 = identity>
     requires MergeMovable<IteratorType<Rng1>, IteratorType<Rng2>, 0, Comp, Proj1, Proj2>
     tuple<IteratorType<Rng1>, IteratorType<Rng2>, 0>
       merge_move(Rng1& rng1, Rng2& rng2, O result,
             Comp comp = Comp{}, Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
        Effects: Moves all the elements of the two ranges [first1,last1) and [first2,last2) into the range
        [result_result_last), where result_last is result + (last1 - first1) + (last2 - first2),
        such that the resulting range satisfies [Editor's note: TODO The following postcondition isn't well-
        formed:] is_sorted(result, result_last, comp).
7
        Requires: The ranges [first1,last1) and [first2,last2) shall be sorted with respect to comp,
        proj1, and proj2. The resulting range shall not overlap with either of the original ranges.
8
        Returns: make_tuple(last1, last2, result + (last1 - first1) + (last2 - first2)).
9
        Complexity: At most (last1 - first1) + (last2 - first2) - 1 applications of the comparison
        function and each projection.
10
        Remarks: Stable (17.6.5.7).
   template < class BidirectionalIterator>
     void inplace_merge(BidirectionalIterator first,
                        BidirectionalIterator middle,
                        BidirectionalIterator last);
   template < class BidirectionalIterator, class Compare >
     void inplace_merge(BidirectionalIterator first,
                        BidirectionalIterator middle,
                        BidirectionalIterator last, Compare comp);
   template<BidirectionalIterator I, Sentinel<I> S, class Comp = less<>,
       class Proj = identity>
     requires Sortable<I, Comp, Proj>
       inplace_merge(I first, I middle, S last, Comp comp = Comp{}, Proj proj = Proj{});
   template<Bidirectional <a href="IterableRange">IterableRange</a> Rng, class Comp = less<>, class Proj = identity>
     requires Sortable < Iterator Type < Rng > , Comp, Proj >
     IteratorType<Rng>
       inplace_merge(Rng& rng, IteratorType<Rng> middle, Comp comp = Comp{},
                     Proj proj = Proj{});
```

§ 25.4.4 145

Effects: Merges two sorted consecutive ranges [first,middle) and [middle,last), putting the result of the merge into the range [first,last). The resulting range will be in non-decreasing order; that is, for every iterator i in [first,last) other than first, the condition \*i < \*(i - 1) or, respectively, comp(\*i, \*(i - 1)) INVOKE (comp, INVOKE (proj, \*i), INVOKE (proj, \*(i - 1))) will be false.

- Requires: The ranges [first,middle) and [middle,last) shall be sorted with respect to operator or comp\_and\_proj. BidirectionalIterator shall satisfy the requirements of ValueSwappable (19.2.18).

  The type of \*first shall satisfy the requirements of MoveConstructible (Table 20) and of MoveAssignable (Table 22).
- 13 Returns: last

2

- Complexity: When enough additional memory is available, (last first) 1 comparisons applications of the comparison function and projection. If no additional memory is available, an algorithm with complexity  $N \log(N)$  (where N is equal to last first) may be used.
- 15 Remarks: Stable (17.6.5.7).

#### 25.4.5 Set operations on sorted structures

of the comparison function and projections.

[alg.set.operations]

<sup>1</sup> This section defines all the basic set operations on sorted structures. They also work with multisets (23.4.7) containing multiple copies of equivalent elements. The semantics of the set operations are generalized to multisets in a standard way by defining set\_union() to contain the maximum number of occurrences of every element, set\_intersection() to contain the minimum, and so on.

25.4.5.1 includes [includes]

```
template<class InputIterator1, class InputIterator2>
 bool includes(InputIterator1 first1, InputIterator1 last1,
                InputIterator2 first2, InputIterator2 last2);
template < class InputIterator1, class InputIterator2, class Compare >
 bool includes(InputIterator1 first1, InputIterator1 last1,
                InputIterator2 first2, InputIterator2 last2,
                Compare comp);
template<InputIterator I1, Sentinel<I1> S1, InputIterator I2, Sentinel<I2> S2,
    class Proj1 = identity, class Proj2 = identity,
    IndirectCallableRelationStrictWeakOrder<Projected<I1, Proj1>, Projected<I2, Proj2>> Comp = less<>>
    includes(I1 first1, S1 last1, I2 first2, S2 last2, Comp comp = Comp{},
             Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
template < Input Iterable Range Rng1, Input Iterable Range Rng2, class Proj1 = identity,
    class Proj2 = identity,
    IndirectCallableRelationStrictWeakOrder<Projected<IteratorType<Rng1>, Proj1>,
      Projected<IteratorType<Rng2>, Proj2>> Comp = less<>>
  bool
    includes(Rng1&& rng1, Rng2&& rng2, Comp comp = Comp{},
             Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
     Returns: true if [first2,last2) is empty or if every element in the range [first2,last2) is con-
     tained in the range [first1,last1). Returns false otherwise.
     Complexity: At most 2 * ((last1 - first1) + (last2 - first2)) - 1 comparisons applications
```

25.4.5.2 set\_union [set.union]

§ 25.4.5.2

```
template < class InputIterator1, class InputIterator2,
         class OutputIterator>
 OutputIterator
    set_union(InputIterator1 first1, InputIterator1 last1,
              InputIterator2 first2, InputIterator2 last2,
              OutputIterator result);
template < class InputIterator1, class InputIterator2,
         class OutputIterator, class Compare>
 OutputIterator
    set_union(InputIterator1 first1, InputIterator1 last1,
              InputIterator2 first2, InputIterator2 last2,
              OutputIterator result, Compare comp);
template<InputIterator I1, Sentinel<I1> S1, InputIterator I2, Sentinel<I2> S2,
    WeaklyIncrementable 0, class Comp = less<>, class Proj1 = identity, class Proj2 = identity,
    IndirectCallableRelation<Projected<I1, Proj1>, Projected<I2, Proj2> Comp = less<>>
  requires Mergeable<I1, I2, O, Comp, Proj1, Proj2>
  tuple<I1, I2, O>
    set_union(I1 first1, S1 last1, I2 first2, S2 last2, O result, Comp comp = Comp{},
              Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
template<InputIterableRange Rng1, InputIterableRange Rng2, WeaklyIncrementable O,
    class Comp = less<>, class Proj1 = identity, class Proj2 = identity;
    IndirectCallableRelation<Projected<IteratorType<Rng1>, Proj1>,
      Projected<IteratorType<Rng2>, Proj2» Comp = less<> >
  requires Mergeable<IteratorType<Rng1>, IteratorType<Rng2>, 0, Comp, Proj1, Proj2>
  tuple<IteratorType<Rng1>, IteratorType<Rng2>, 0>
    set_union(Rng1& rng1, Rng2& rng2, O result, Comp comp = Comp{},
              Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
     Effects: Constructs a sorted union of the elements from the two ranges; that is, the set of elements
     that are present in one or both of the ranges.
     Requires: The resulting range shall not overlap with either of the original ranges.
     Returns: The end of the constructed range make_tuple(last1, last2, result + n), where n is the
     number of elements in the constructed range.
     Complexity: At most 2 * ((last1 - first1) + (last2 - first2)) - 1 comparisons applications
     of the comparison function and projections.
     Remarks: If [first1,last1) contains m elements that are equivalent to each other and [first2,
     last2) contains n elements that are equivalent to them, then all m elements from the first range shall
     be copied to the output range, in order, and then \max(n-m,0) elements from the second range shall
     be copied to the output range, in order.
                                                                                    [set.intersection]
25.4.5.3 set_intersection
template < class InputIterator1, class InputIterator2,
         class OutputIterator>
  OutputIterator
    set_intersection(InputIterator1 first1, InputIterator1 last1,
                     InputIterator2 first2, InputIterator2 last2,
                     OutputIterator result);
template < class InputIterator1, class InputIterator2,
         class OutputIterator, class Compare>
§ 25.4.5.3
                                                                                                  147
```

1

```

§ 25.4.5.5

1 Effects: Copies the elements of the range [first1,last1) that are not present in the range [first2, last2), and the elements of the range [first2,last2) that are not present in the range [first1, last1) to the range beginning at result. The elements in the constructed range are sorted.

- 2 Requires: The resulting range shall not overlap with either of the original ranges.
- 3 Returns: The end of the constructed range make tuple (last1, last2, result + n), where n is the number of elements in the constructed range.
- 4 Complexity: At most 2 \* ((last1 - first1) + (last2 - first2)) - 1 comparisons applications of the comparison function and projections.
- 5 Remarks: If [first1,last1) contains m elements that are equivalent to each other and [first2, last2) contains n elements that are equivalent to them, then |m-n| of those elements shall be copied to the output range: the last m-n of these elements from [first1,last1) if m>n, and the last n-m of these elements from [first2,last2) if m < n.

#### 25.4.6 Heap operations

#### [alg.heap.operations]

- 1 A heap is a particular organization of elements in a range between two random access iterators [a,b). Its two key properties are:
  - (1) There is no element greater than \*a in the range and
  - (2) \*a may be removed by pop\_heap(), or a new element added by push\_heap(), in  $\mathcal{O}(\log(N))$  time.
- <sup>2</sup> These properties make heaps useful as priority queues.
- 3 make\_heap() converts a range into a heap and sort\_heap() turns a heap into a sorted sequence.

[push.heap] 25.4.6.1 push\_heap

```
template<class RandomAccessIterator>
  void push_heap(RandomAccessIterator first, RandomAccessIterator last);
template < class Random Access Iterator, class Compare >
  void push heap(RandomAccessIterator first, RandomAccessIterator last,
                 Compare comp);
template<RandomAccessIterator I, Sentinel<I> S, class Comp = less<>,
    class Proj = identity>
 requires Sortable<I, Comp, Proj>
  I push_heap(I first, S last, Comp comp = Comp{}, Proj proj = Proj{});
template<RandomAccessIterableRange Rng, class Comp = less<>, class Proj = identity>
  requires Sortable<IteratorType<Rng>, Comp, Proj>
  IteratorType<Rng>
    push_heap(Rng& rng, Comp comp = Comp{}, Proj proj = Proj{});
```

- 1 Effects: Places the value in the location last - 1 into the resulting heap [first,last).
- 2 Requires: The range [first,last - 1) shall be a valid heap. The type of \*first shall satisfy the MoveConstructible requirements (Table 20) and the MoveAssignable requirements (Table 22).
- 3 Returns: last
- 4 Complexity: At most log(last - first) comparisons applications of the comparison function and projection.

§ 25.4.6.1 150

```
25.4.6.2 pop_heap
                                                                                          [pop.heap]
template < class Random AccessIterator >
  void pop_heap(RandomAccessIterator first, RandomAccessIterator last);
template<class RandomAccessIterator, class Compare>
  void pop_heap(RandomAccessIterator first, RandomAccessIterator last,
                Compare comp);
template<RandomAccessIterator I, Sentinel<I> S, class Comp = less<>,
    class Proj = identity>
  requires Sortable<I, Comp, Proj>
  I pop_heap(I first, S last, Comp comp = Comp{}, Proj proj = Proj{});
template<RandomAccessIterableRange Rng, class Comp = less<>, class Proj = identity>
  requires Sortable<IteratorType<Rng>, Comp, Proj>
  IteratorType<Rng>
    pop_heap(Rng& rng, Comp comp = Comp{}, Proj proj = Proj{});
     Requires: The range [first,last) shall be a valid non-empty heap. RandomAccessIterator shall
     satisfy the requirements of ValueSwappable (19.2.18). The type of *first shall satisfy the requirements
     of MoveConstructible (Table 20) and of MoveAssignable (Table 22).
     Effects: Swaps the value in the location first with the value in the location last - 1 and makes
     [first,last - 1) into a heap.
     Returns: last
     Complexity: At most 2 * log(last - first) comparisons applications of the comparison function
     and projection.
                                                                                        [make.heap]
25.4.6.3 make_heap
template < class Random Access Iterator >
  void make_heap(RandomAccessIterator first, RandomAccessIterator last);
template<class RandomAccessIterator, class Compare>
  void make_heap(RandomAccessIterator first, RandomAccessIterator last,
                 Compare comp);
template<RandomAccessIterator I, Sentinel<I> S, class Comp = less<>,
    class Proj = identity>
 requires Sortable<I, Comp, Proj>
  I make_heap(I first, S last, Comp comp = Comp{}, Proj proj = Proj{});
template<RandomAccessIterableRange Rng, class Comp = less<>, class Proj = identity>
  requires Sortable<IteratorType<Rng>, Comp, Proj>
  IteratorType<Rng>
   make_heap(Rng& rng, Comp comp = Comp{}, Proj proj = Proj{});
     Effects: Constructs a heap out of the range [first,last).
     Requires: The type of *first shall satisfy the MoveConstructible requirements (Table 20) and the
     MoveAssignable requirements (Table 22).
     Returns: last
     Complexity: At most 3 * (last - first) comparisons applications of the comparison function and
     projection.

    I sort_heap(I first, S last, Comp comp = Comp{}, Proj proj = Proj{});
  template<RandomAccessIterableRange Rng, class Comp = less<>, class Proj = identity>
    requires Sortable<IteratorType<Rng>, Comp, Proj>
    IteratorType<Rng>
      sort_heap(Rng& rng, Comp comp = Comp{}, Proj proj = Proj{});
        Effects: Sorts elements in the heap [first,last).
2
        Requires: The range [first,last) shall be a valid heap. RandomAccessIterator shall satisfy the
       requirements of ValueSwappable (19.2.18). The type of *first shall satisfy the requirements of
       MoveConstructible (Table 20) and of MoveAssignable (Table 22).
3
        Returns: last
        Complexity: At most N \log(N) comparisons (where N == last - first).
                                                                                              [is.heap]
  25.4.6.5
            is_heap
    template < class Random Access Iterator >
      bool is_heap(RandomAccessIterator first, RandomAccessIterator last);
  template<RandomAccessIterator I, Sentinel<I> S, class Proj = identity,
      IndirectCallableRelationStrictWeakOrder<Projected<I, Proj>> Comp = less<>>
    bool is_heap(I first, S last, Comp comp = Comp{}, Proj proj = Proj{});
  template<RandomAccessIterableRange Rng, class Proj = identity,</pre>
      IndirectCallableRelationStrictWeakOrder<Projected<IteratorType<Rng>, Proj>> Comp = less<>>
      is_heap(Rng&& rng, Comp comp = Comp{}, Proj proj = Proj{});
1
        Returns: is_heap_until(first, last, comp, proj) == last
    template<class RandomAccessIterator, class Compare>
      bool is_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
        Returns: is_heap_until(first, last, comp) == last
    template < class Random Access Iterator >
      RandomAccessIterator is_heap_until(RandomAccessIterator first, RandomAccessIterator last);
    template<class RandomAccessIterator, class Compare>
      RandomAccessIterator is_heap_until(RandomAccessIterator first, RandomAccessIterator last,
        Compare comp);
  template<RandomAccessIterator I, Sentinel<I> S, class Proj = identity,
      IndirectCallableRelationStrictWeakOrder<Projected<I, Proj>> Comp = less<>>
    I is_heap_until(I first, S last, Comp comp = Comp{}, Proj proj = Proj{});
```

§ 25.4.6.5

```
template < Random Access <a href="Iterable-Range">Iterable-Range</a> Rng, class Proj = identity,
      IndirectCallableRelationStrictWeakOrder<Projected<IteratorType<Rng>, Proj>> Comp = less<>>
    IteratorType<Rng>
      is_heap_until(Rng& rng, Comp comp = Comp{}, Proj proj = Proj{});
3
        Returns: If distance(first, last) < 2, returns last. Otherwise, returns the last iterator i in
        [first,last] for which the range [first,i) is a heap.
4
        Complexity: Linear.
  25.4.7 Minimum and maximum
                                                                                         [alg.min.max]
  template < class T > constexpr const T& min(const T& a, const T& b);
  template < class T, class Compare >
    constexpr const T& min(const T& a, const T& b, Compare comp);
  template<TotallyOrdered T>
    constexpr const T& min(const T& a, const T& b);
  template < class T, class Comp>
    requires RelationStrictWeakOrder<FunctionType<Comp>, T>
    constexpr const T& min(const T& a, const T& b, Comp comp);
        Requires: Type T is LessThanComparable (Table 18).
2
        Returns: The smaller value.
3
        Remarks: Returns the first argument when the arguments are equivalent.
  template<class T>
    constexpr T min(initializer_list<T> t);
  template < class T, class Compare >
    constexpr T min(initializer_list<T> t, Compare comp);

   § 25.4.7
                                                                                                      154
```

11

```
requires RelationStrictWeakOrder<FunctionType<Comp>, T>
     constexpr pair<const T&, const T&>
       minmax(const T& a, const T& b, Comp comp);
13
         Requires: Type T shall be LessThanComparable (Table 18).
14
         Returns: pair<const T&, const T&>(b, a) if b is smaller than a, and pair<const T&, const
         T&>(a, b) otherwise.
15
         Remarks: Returns pair<const T&, const T&>(a, b) when the arguments are equivalent.
16
         Complexity: Exactly one comparison.
   template<class T>
     constexpr pair<T, T> minmax(initializer_list<T> t);
   template < class T, class Compare >
     constexpr pair<T, T> minmax(initializer_list<T> t, Compare comp);

       IndirectCallableRelationStrictWeakOrder<IteratorType<Rng>> Comp>
     requires Semiregular<ValueType<IteratorType<Rng>>>
     pair<ValueType<IteratorType<Rng>>, ValueType<IteratorType<Rng>>>
       minmax(Rng&& rng, Comp comp);
17
         Requires: TisLessThanComparable and CopyConstructible and t.size() > 0distance(begin(rng),
         end(rng)) > 0.
18
         Returns: pair<T, T>(x, y), where x has the smallest and y has the largest value in the initializer
         list or range.
19
         Remarks: x is a copy of the leftmost argument when several arguments are equivalent to the smallest.
         y is a copy of the rightmost argument when several arguments are equivalent to the largest.
20
         Complexity: At most (3/2) * t.size()(3/2) * distance(begin(rng), end(rng)) applications of
         the corresponding predicate.
   template < class ForwardIterator>
     ForwardIterator min_element(ForwardIterator first, ForwardIterator last);
   template < class Forward Iterator, class Compare >
     ForwardIterator min_element(ForwardIterator first, ForwardIterator last,
                                Compare comp);

     IteratorType<Rng>
       max_element(Rng& rng, Comp comp = Comp{}, Proj proj = Proj{});
23
         Returns: The first iterator i in the range [first,last) such that for every iterator j in the range [
        first, last) the following corresponding conditions hold: !(*i < *j) or comp(*i, *j) == false INVOKE (comp,
         INVOKE(proj, *i), INVOKE(proj, *j)) == false. Returns last if first == last.
24
         Complexity: Exactly max((last - first) - 1, 0) applications of the corresponding comparisons
        function and projection.
   template<class ForwardIterator>
     pair<ForwardIterator, ForwardIterator>
       minmax_element(ForwardIterator first, ForwardIterator last);
   template < class Forward Iterator, class Compare >
     pair<ForwardIterator, ForwardIterator>
       minmax_element(ForwardIterator first, ForwardIterator last, Compare comp);
   template<ForwardIterator I, Sentinel<I> S, class Proj = identity,
       IndirectCallableRelationStrictWeakOrder<Projected<I, Proj>> Comp = less<>>
     pair<I, I>
       minmax_element(I first, S last, Comp comp = Comp{}, Proj proj = Proj{});
   template<Forward Iterable Range Rng, class Proj = identity,
       IndirectCallableRelationStrictWeakOrder<Projected<IteratorType<Rng>, Proj>> Comp = less<>>
     pair<IteratorType<Rng>, IteratorType<Rng>>
       minmax_element(Rng& rng, Comp comp = Comp{}, Proj proj = Proj{});
25
        Returns: make_pair(first, first) if [first,last) is empty, otherwise make_pair(m, M), where
        m is the first iterator in [first,last) such that no iterator in the range refers to a smaller element,
        and where M is the last iterator in [first,last) such that no iterator in the range refers to a larger
26
         Complexity: At most max(|\frac{3}{2}(N-1)|,0) applications of the corresponding predicate comparison
        function and projection, where N is distance(first, last).
```

§ 25.4.7

#### 25.4.8 Lexicographical comparison

[alg.lex.comparison]

```
template<class InputIterator1, class InputIterator2>
 bool
    lexicographical_compare(InputIterator1 first1, InputIterator1 last1,
                            InputIterator2 first2, InputIterator2 last2);
template < class InputIterator1, class InputIterator2, class Compare >
    lexicographical_compare(InputIterator1 first1, InputIterator1 last1,
                            InputIterator2 first2, InputIterator2 last2,
                            Compare comp);
template<InputIterator I1, Sentinel<I1> S1, InputIterator I2, Sentinel<I2> S2,
    class Proj1 = identity, class Proj2 = identity,
    IndirectCallableRelationStrictWeakOrder<Projected<I1, Proj1>, Projected<I2, Proj2>> Comp = less<>>
 bool
    lexicographical_compare(I1 first1, S1 last1, I2 first2, S2 last2,
                            Comp comp = Comp{}, Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
template < Input Iterable Range Rng1, Input Iterable Range Rng2, class Proj1 = identity,
    class Proj2 = identity,
    IndirectCallableRelationStrictWeakOrder<Pre>Projected<IteratorType<Rng1>, Proj1>,
      Projected<IteratorType<Rng2>, Proj2>> Comp = less<>>
 bool
    lexicographical_compare(Rng1&& rng1, Rng2&& rng2, Comp comp = Comp{},
                            Proj1 proj1 = Proj1{}, Proj2 proj2 = Proj2{});
```

- Returns: true if the sequence of elements defined by the range [first1,last1) is lexicographically less than the sequence of elements defined by the range [first2,last2) and false otherwise.
- Complexity: At most 2\*min((last1 first1), (last2 first2)) applications of the corresponding comparison and projection.
- Remarks: If two sequences have the same number of elements and their corresponding elements are equivalent, then neither sequence is lexicographically less than the other. If one sequence is a prefix of the other, then the shorter sequence is lexicographically less than the longer sequence. Otherwise, the lexicographical comparison of the sequences yields the same result as the comparison of the first corresponding pair of elements that are not equivalent.

```
for ( ; first1 != last1 && first2 != last2 ; ++first1, ++first2) {
   if (*first1 < *first2) return true;
   if (*first2 < *first1) return false;
}
return first1 == last1 && first2 != last2;

using namespace placeholders;
auto&& cmp1 = bind(comp, bind(proj1, _1), bind(proj2, _2));
auto&& cmp2 = bind(comp, bind(proj2, _1), bind(proj1, _2));
for ( ; first1 != last1 && first2 != last2 ; ++first1, ++first2) {
   if (cmp1(*first1, *first2)) return true;
   if (cmp2(*first2, *first1)) return false;
}
return first1 == last1 && first2 != last2;</pre>
```

4 Remarks: An empty sequence is lexicographically less than any non-empty sequence, but not less than any empty sequence.

§ 25.4.8 157

#### 25.4.9 Permutation generators

1

2

3

4

5

6

7

#### [alg.permutation.generators]

```
template < class BidirectionalIterator>
 bool next_permutation(BidirectionalIterator first,
                        BidirectionalIterator last);
template<class BidirectionalIterator, class Compare>
 bool next_permutation(BidirectionalIterator first,
                        BidirectionalIterator last, Compare comp);
template<BidirectionalIterator I, Sentinel<I> S, class Comp = less<>,
    class Proj = identity, IndirectCallableRelation<Projected<I, Proj> > Comp = less<>>
  requires Sortable<I, Comp, Proj>
 bool next_permutation(I first, S last, Comp comp = Comp{}, Proj proj = Proj{});
template<BidirectionalIterableRange Rng, class Comp = less<>,
    class Proj = identity, IndirectCallableRelation<Projected<IteratorType<Rng>, Proj> > Comp = less<>>
  requires Sortable<IteratorType<Rng>, Comp, Proj>
 bool
    next_permutation(Rng&& rng, Comp comp = Comp{}, Proj proj = Proj{});
     Effects: Takes a sequence defined by the range [first,last) and transforms it into the next permu-
     tation. The next permutation is found by assuming that the set of all permutations is lexicographically
     sorted with respect to operator or comp and proj. If such a permutation exists, it returns true.
     Otherwise, it transforms the sequence into the smallest permutation, that is, the ascendingly sorted
     one, and returns false.
     Requires: BidirectionalIterator shall satisfy the requirements of ValueSwappable (19.2.18).
     Complexity: At most (last - first)/2 swaps.
template < class BidirectionalIterator>
  bool prev_permutation(BidirectionalIterator first,
                        BidirectionalIterator last);
template < class BidirectionalIterator, class Compare >
 bool prev_permutation(BidirectionalIterator first,
                        BidirectionalIterator last, Compare comp);
template<BidirectionalIterator I, Sentinel<I> S, class Comp = less<>,
    class Proj = identity, IndirectCallableRelation<Projected<I, Proj> > Comp = less<>>
  requires Sortable<I, Comp, Proj>
 bool prev_permutation(I first, S last, Comp comp = Comp{}, Proj proj = Proj{});
template<Bidirectional Iterable Range Rng, class Comp = less<>,
    class Proj = identity, IndirectCallableRelation<Projected<IteratorType<Rng>, Proj> > Comp = less<>>
 requires Sortable<IteratorType<Rng>, Comp, Proj>
    prev_permutation(Rng&& rng, Comp comp = Comp{}, Proj proj = Proj{});
     Effects: Takes a sequence defined by the range [first,last) and transforms it into the previous
     permutation. The previous permutation is found by assuming that the set of all permutations is
     lexicographically sorted with respect to operator or comp and proj.
     Returns: true if such a permutation exists. Otherwise, it transforms the sequence into the largest
     permutation, that is, the descendingly sorted one, and returns false.
     Requires: BidirectionalIterator shall satisfy the requirements of ValueSwappable (19.2.18).
     Complexity: At most (last - first)/2 swaps.
```

§ 25.4.9

#### 25.5 C library algorithms

[alg.c.library]

<sup>1</sup> Table 7 describes some of the contents of the header <cstdlib>.

bsearch(const void \*, const void \*, size\_t, size\_t,

Table 7 — Header <cstdlib> synopsis

Type	Name	e(s)
Type:	size_t	
Functions:	bsearch	qsort

- <sup>2</sup> The contents are the same as the Standard C library header <stdlib.h> with the following exceptions:
- <sup>3</sup> The function signature:

both of which have the same behavior as the original declaration.

4 The function signature:

both of which have the same behavior as the original declaration. The behavior is undefined unless the objects in the array pointed to by base are of trivial type.

[Note: Because the function argument compar() may throw an exception, bsearch() and qsort() are allowed to propagate the exception (17.6.5.12). — end note]

See also: ISO C 7.10.5.

§ 25.5 159

### 26 Numerics library

### [numerics]

#### 26.5 Random number generation

[rand]

26.5.1 Requirements

[rand.req]

26.5.1.3 Uniform random number generator requirements

[rand.req.urng]

```
namespace std {
  template <class G>
  concept bool UniformRandomNumberGenerator =
    requires(G g) {
     typename ResultType<G>;
     requires UnsignedIntegral<ResultType<G>>;
     { g() } -> Same<ResultType<G>>;
     { G::min() } -> Same<ResultType<G>>;
     { G::max() } -> Same<ResultType<G>>;
     };
};
```

<sup>1</sup> A uniform random number generator g of type G is a function object returning unsigned integer values such that each value in the range of possible results has (ideally) equal probability of being returned. [Note: The degree to which g's results approximate the ideal is often determined statistically. —end note]

[Editor's note: Remove para 2 and 3 and Table 116 (Uniform random number generator requirements).]

<sup>2</sup> Let g be any object of type G. Then type G models UniformRandomNumberGenerator if and only if

```
(2.1) — Both G::min() and G::max() are constant expressions (5.19).
```

```
(2.2) — (G::min() < G::max()) != false.
```

- (2.3)  $(G::min() \le g() \le G::max()) != false.$
- (2.4) g() has amortized constant complexity.

§ 26.5.1.3

# Annex A (informative) Acknowledgements [acknowledgements]

<sup>1</sup> I would like to thank Andrew Sutton for his work on the Concepts TS (1.2), for his help formalizing the ideas of the range-v3 library [?] on which this work is based, and for his review of this document.

- <sup>2</sup> Sean Parent has made major contributions to both the foundations and the wording of this peper.
- <sup>3</sup> Stephan T. Lavavej offered a careful review of much of this document, a non-trivial undertaking.
- <sup>4</sup> I would also like to thank the members of the Ranges SG who offered feedback on early drafts; especially, Tony Van Eerd, Casey Carter, and Walter Brown.

Acknowledgements 161

# Annex B (informative) Compatibility

[diff]

#### B.1 C++ and Ranges

[diff.cpp]

<sup>1</sup> This section details the known breaking changes likely to effect user code when being ported to the version of the Standard Library described in this document.

#### **B.1.1** Algorithm Return Types

[diff.cpp.algo\_return]

- <sup>1</sup> The algorithms described in this document permit the type of the end sentinel to differ from the type of the begin iterator. This is so that the algorithms can operate on ranges for which the physical end position is not yet known.
- <sup>2</sup> The physical end position of the input range is determined during the execution of many of the algorithms. Rather than lose that potentially useful information, the design presented here has such algorithms return the iterator position of the end of the range. In many cases, this is a breaking change. Some algorithms that return iterators in today's STL are changed to return pairs, and algorithms that return pairs today are changed to return tuples. This is likely to be the most noticeable breaking change.
- 3 Alternate designs that were less impactful were considered and dismissed. See Section 3.3.6 in N4128 (1.2) for a discussion of the issues.

#### **B.1.2** Stronger Constraints

[diff.cpp.constraints]

- <sup>1</sup> In this proposal, many algorithms and utilities get stricter type checking. For example, algorithms constrained with LessThanComparable today are constrained by TotallyOrdered in this document. This concept requires types to provide *all* the relational operators, not just operator<.
- <sup>2</sup> The use of coarser-grained, higher-level concepts in algorithm constraints is to make the type checks more semantic in nature and less syntactic. It also has the benefit of being less verbose while giving algorithm implementors greater implementation freedom. This approach is in contrast to the previous effort to add concepts to the Standard Library in the C++0x timeframe, which saw a proliferation of small, purely syntactic concepts and algorithm constraints that merely restated the algorithms' implementation details more verbosely in the algorithms' function signatures.
- <sup>3</sup> The potential for breakage must be carefully weighed against the integrity and complexity of the constraints system. The coarseness of the concepts may need to change in response to real-world usage.

#### **B.1.3** Constrained Functional Objects

[diff.cpp.functional]

- The algorithm design described in this document assumes that the function objects std::equal\_to and std::less get constraints added to their function call operators. (The former is constrained with Equality-Comparable and the latter with TotallyOrdered). Similar constraints are added to the other function objects in <functional>. Also, the so-called transparent relational function objects (less<void> and friends) have their return type coerced to bool. As with the coarsely-grained algorithm constraints, these function object constraints are likely to cause user code to break.
- Real-world experience is needed to assess the seriousness of the breakage. From a correctness point of view, the constraints are logical and valuable, but it's possible that for the sake of compatibility we provide both constrained and unconstrained functional objects.

§ B.1.3

#### B.1.4 Iterators and Default-Constructibility

#### [diff.cpp.defaultconstruct]

- <sup>1</sup> In today's STL, iterators need not be default-constructible. The Iterator concept described in this document requires default-constructibility. This could potentially cause breakage in users' code. Also, it makes the implementation of some types of iterators more complicated. Any iterator that has members that are not default constructible (e.g., an iterator that contains a lambda that has captured by reference) must take special steps to provide default-constructibility (e.g., by wrapping non-default-constructible types in std::optional). This can weaken class invariants.
- <sup>2</sup> The guarantee of default-constructibility simplifies the implementation of much iterator- and range-based code that would otherwise need to wrap iterators in std::optional. But the needs of backward-compatibility, the extra complexity to iterator implementors, and the weakened invariants may prove to be too great a burden.
- <sup>3</sup> We may in fact go even farther and remove the requirement of default-constructibility from the Semiregular concept. Time and experience will give us guidance here.

#### B.1.5 iterator traits cannot be specialized

#### [diff.cpp.iteratortraits]

- In this STL design, iterator\_traits changes from being a class template to being an alias template. This is to intentionally break any code that tries to specialize it. In its place are the three class templates difference\_type, value\_type, and iterator\_category. The need for this traits balkanization is because the associated types belong to separate concepts: difference\_type belongs to WeaklyIncrementable; value\_type belongs to Readable; and iterator\_category belongs to WeakInputIterator.
- <sup>2</sup> This breakage is intentional and inherent in the decomposition of the iterator concepts established by The Palo Alto report (1.2).

#### B.2 Ranges and the Palo Alto TR (N3351)

[diff.n3351]

<sup>1</sup> The Palo Alto report (1.2) presents a comprehensive design for the Standard Template Library constrained with concepts. It served both as a basis for the Concepts Lite language feature and for this document. However, this document diverges from the Palo Alto report in small ways. The differences are in the interests of backwards compatability, to avoid confusing a large installed base of programmers already familiar with the STL, and to keep the scope of this document as small as possible. This section describes the ways in which the two suggested designs differ.

#### B.2.1 Sentinels

[diff.n3351.sentinels]

- <sup>1</sup> In the design presented in this document, the type of a range's end delimitter may differ from the iterator representing the range's start position. The reasons for this change are discribed in N4128 (1.2). This causes a number of difference from the Palo Alto report:
- (1.1) The algorithms get an additional constraint for the sentinel.
- (1.2) The return types of the algorithms are changed as described above (B.1.1).
- (1.3) Some algorithms have operational semantics that require them to know the physical end position (e.g., reverse). Those algorithms must make an  $\mathcal{O}(N)$  probe for the end position before proceeding. This does not change the operational semantics of any code that is valid today (the probe is unnecessary when the types of the begin and end are the same), and even when the probe is needed, in no cases does this change the compexity guarantee of any algorithm.

#### **B.2.2** Callables and Projections

[diff.n3351.invok\_proj]

Adobe's Source Libraries [?] pioneered the use of *callables* and *projections* in the standard algorithms. Callables let users pass member pointers where the algorithms expect callables, saving users the trouble of using a binder or a lambda. Projections are extra optional arguments that give users a way to trivially

§ B.2.2

transform input data on the fly during the execution of the algorithms. Neither significantly changes the operational semantics of the algorithms, but they do change the form of the algorithm constraints. To deal with the extra complexity of the constraints, the design presented here adds higher-level composite concepts for concisely expressing the necessary relationships between callables, iterators, and projections.

#### B.2.3 No Distinct DistanceType Associated Type [diff.n3351.distance\_type]

In the Palo Alto report, the WeaklyIncrementable concept has an associated type called DistanceType, and the RandomAccessIterator concepts adds another associated type called DifferenceType. The latter is required to be convertible to the former, but they are not required to be the same type. (DifferenceType is required to be a signed integral type, but DistanceType need not be signed.) Although sensible from a soundness point of view, the author of this paper feels this is potentially a rich source of confusion. This paper hews closer to the current standard by having only one associated type, DifferenceType, and requiring it to be signed.

# B.2.4 Distance Primitive is O(1) for Random Access Iterators [diff.n3351.distance\_algo]

In the Palo Alto report, the **distance** iterator primitive for computing the distance from one iterator position to another is not implemented in terms of **operator**- for random access iterators. **distance**, according to the report, should always be  $\mathcal{O}(N)$ . It reads:

The standard mandates a different definition for random access iterators: distance(i, j) == j - i. We see this as a specification error; the guarantees of the distance operation have been weakened for an iterator specialization.

In our design, we consider the two operations to be distinct.

The design presented in this document keeps the specialization for random access iterators. To do otherwise would be to silently break complexity guarantees in an unknown amount of working code.

To address the concern about weakened guarantees of the distance primitive, the design presented here requires that random access iterators model SizedIteratorRange (24.5.1). The SizedIteratorRange concept requires that b - a return the number of times a would have to be incremented to make it compare equal to b. Any type purporting to be a random access iterator that fails to meet that requirement is by definition not a valid random access iterator.

#### **B.2.5** Output Iterators

#### [diff.n3351.output\_iters]

The Palo Alto report does not define concepts for output iterators, making do with WeaklyIncrementable, Writable, and (where needed) EqualityComparable. The author of this document sees little downside to grouping these into the familiar OutputIterator concept and the more freequently-needed WeakOutputIterator. Even if they are not strictly needed, their absence would be surprising.

#### **B.2.6** No Algorithm Reformulations

#### [diff.n3351.no eop algos]

Between the standardization of the Standard Library and the Palo Alto report, much new research was done to further generalize the standard algorithms (see "Element of Programming", Stepanov, McJones [?]). The algorithms presented in The Palo Alto report reflect the results of that research in the algorithm constraints, some of which (e.g., sort, inplace\_merge) take iterators with weaker categories than they do in the current standard. The design presented in this document does not reflect those changes. Although those changes are desirable, generalizing the algoritms as described in The Palo Alto report feels like it would be best done in a separate proposal.

§ B.2.6

## Annex C (informative) Future Work

[future]

<sup>1</sup> This document brings ranges and concepts to a minimal useful subset of the Standard Library. A proper and full implementation has many more moving parts. In addition, we can use the opportunity this work presents to address long-standing shortcomings in the Standard Library. Some of these future work items are described below.

#### C.1 Implementation Experience with Concepts

[future.experience]

The ideas presented here have been vetted in the range-v3 ([?]) library, which has seen both heavy development and heavy use over the past year and a half. However, this library is implemented in C++11 with the help of a library-based emulation layer for Concepts Lite. Andrew Sutton's origin ([?]) library implements many of these ideas using real concepts, but it's a subset of the work presented here. A critically important piece of this work will be to fully implement this design in C++17 with a compiler that supports Concepts.

#### C.2 Algorithms and Rvalue Ranges

[future.rvalrngs]

- As presented in this document, the vast majority of algorithms do not accept rvalue <a href="Iterables-Ranges">Iterables-Ranges</a>. This shortcoming becomes more painful with the addition of range views (C.5). The issue is one of safety. Those algorithms that return iterators into the input range, like find, can return iterators that will immediately be made invalid once the temporary <a href="Iterable-Range">Iterable-Range</a> they point into gets destroyed but not for all <a href="Iterables-Ranges">Iterable-Range</a> For an <a href="Iterable-Range">Iterable-Range</a> after the <a href="Iterable-Range">Iterable-Range</a> has been destroyed. The iterator's validity is not tied to the <a href="Iterable-Range">Iterable-Range</a> slifetime at all.
- <sup>2</sup> The range-v3 library ([?]) on which this proposal is based has recently implemented an experimental solution to this problem. The library provides a wrapper called **dangling** that the algorithms can use to mark returned iterators that point into rvalue ranges. It works as follows:

```
template <class T>
struct dangling {
  dangling() = default;
  dangling(T t) : t_(t) {}
  T get_unsafe() const { return t_; } // explicit
private:
  T t_;
};
template < Iterable Range Rng>
using safe_iterator_t =
  std::conditional_t<
    std::is_lvalue_reference<Rng>::value,
    IteratorType<Rng>,
    dangling<IteratorType<Rng>>>;
template <InputIterableRange Rng, class T, class Proj = identity>
  requires //...
  safe_iterator_t<Rng>
    find(Rng&& rng, const T& value, Proj proj = Proj{}) {
      return find(begin(rng), end(rng), value, std::move(proj));
```

}

<sup>3</sup> Of particular note is that a dangling<Iterator> is not an iterator. In order to obtain an iterator into an expired <a href="IterableRange">IterableRange</a>, the user must explicitly call a method called <a href="get\_unsafe">get\_unsafe</a>. That makes it impossible for a user to accidentally use an iterator that may be invalid.

- <sup>4</sup> An extension of this idea would be to define safe\_iterator\_t in terms of a trait that can be specialized on user-defined <a href="https://december.ncbi.nlm.ncbi.
- <sup>5</sup> If time shows that the range-v3 solution is workable, a future paper can integrate the new functionality into this document.

#### C.3 Proxy Iterators

[future.proxy]

- As early at 1998 when Herb Sutter published his "When is a Container not a Container" [?] article, it was known that proxy iterators were a challenge that the current iterator concept hierarchy could not meet. The problem stems from the fact that the ForwardIterator concept as specified in the current standard requires the iterator's reference type to be a true reference, not a proxy. The Palo Alto report lifts this restriction in its respecification of the iterator concepts but doesn't actually solve the problem. The majority of algorithms, once you study the constraints, do not accept many interesting proxy iterator types.
- <sup>2</sup> The author of this document has researched a possible library-only solution to the problem and implemented it in the range-v3 library. (The details of that solution are described in a series of blog posts beginning with "To Be or Not to Be (an Iterator)," Niebler, 2015 [?].) This document does not reflect the results of that research.

Whether and how to best support proxy iterators is left as future work.

#### C.4 Iterator Range Type

#### [future.iterator\_range]

- This paper does not define a concrete type for storing an iterator and a sentinel that models the Range concept. Such a type, like that presented in "A minimal std::range<Iter>," [?] by J. Yasskin would be an obvious addition. Algorithms like equal\_range and rotate could use a concrete range type instead of pair as their return type, improving composability. It would also be useful to implement a view::all range view that yields a lightweight range object that refers to all the elements of a container.
- <sup>2</sup> A future paper will propose such a type.

#### C.5 Range Views and Actions

[future.views]

- <sup>1</sup> The vast majority of the power of ranges comes from their composability. *Views* on existing <u>IterablesRanges</u> can combine in chains of operations that evaluate lazily, giving programmers a concise and efficient way to express rich transformations on data. This paper is narrowly focused on the concepts and the algorithms, leaving range views as critically important future work.
- <sup>2</sup> If range views are composable, non-mutating, lazy algorithms over ranges, then range *actions* are composable, (potentially) mutating, eager algorithms over ranges. Such actions would allow users to send a container through a pipeline to sort it and remove the non-unique elements, for instance. This is something the range views cannot do. Range actions sit along side the views in the programmers toolbox.

#### C.6 Range Facade and Adaptor Utilities

[future.facade]

<sup>1</sup> Until it becomes trivial for users to create their own iterator types, the full potential of iterators will remain unrealized. The range abstraction makes that achievable. With the right library components, it should be possible for users to define a range with a minimal interface (e.g., current, done, and next members), and have iterator types automatically generated. Such a range facade class template is left as future work.

<sup>2</sup> Another common need is to adapt an existing range. For instance, a lazy transform view should be as simple as writing an adaptor that customizes the behavior of a range by passing each element through a transformation function. The specification of a range *adaptor* class template is also left as future work.

#### C.7 Infinite Ranges

[future.infrng]

- 1 It is not hard to define a type that represents an "infinite" range. Imagine a random number generator that keeps generating new random numbers for every application of operator++ and operator\* of its iterator. Indeed, the very existence of the unreachable sentinel type which this document proposes encourages users to think about some ranges as "infinite". The sad reality is that infinite ranges are disallowed by the iterator concept hierarchy as defined in this document.
- <sup>2</sup> The problem with infinite ranges is the requirement that WeaklyIncrementable types have an associated DifferenceType. The DifferenceType must be a built-in integral type, and it must be large enough to hold the distance between any two valid iterators. This is implicit in the fact that the distance iterator primitive returns objects of type DifferenceType.
- <sup>3</sup> Given the fact that there are no infinite precision built-in integral types, the presence of DifferenceType in the concept requirements places a hard upper limit on how big ranges can be. This is a severe limitation.
- <sup>4</sup> Some observations:
- (4.1) Not all possible ranges have finitely countable elements.
- (4.2) Even a range with finitely countable elements may not be countable within the precision of the built-in integral types.
- (4.3) Not all algorithms require the ability to count increments. Algorithms like distance and count require finitely countable iterators, but find and accumulate do not.
  - <sup>5</sup> The above above observations suggest that there is a factorization of the existing concept hierarchy that could solve the problem. Some Incrementables are finitely countable with a built-in integral DifferenceType, and some are not. The algorithms that require countability must say so with an extra requirement.
  - Obviously, some algorithms like accumulate should never be asked to operate on a truly infinite sequence, even if they don't actually maintain counters internally. Such algorithms could still be used with "possibly" infinite sequences. Note that the standard already defines such possibly infinite sequences; for instance, there is no limit in principle to the number of elements in a range delimited with istream\_iterators. It's not hard to imagine other useful possibly- infinite range types: an infinite range that is delimited with a predicate or a sentinel value, for instance. The algorithm requirements should merely enforce that there is no integer overflow possible if the range happens to be larger than can be represented, not necessarily whether the algorithm will terminate or not.

#### C.8 Common Type

#### [future.commontype]

The all-important Common concept relies on the existence of a SFINAE-friendly common\_type trait, which did not make it into C++14. Solving the outstanding issues (active issues: #2460, #2465; and defects: #2408) with common\_type is left as future work on which the correctness of this document depends.

#### C.9 Numeric Algorithms and Containers

[future.numcont]

<sup>1</sup> The numeric algorithms must also be constrained, and additional range-based overloads must be added. Also, the containers should be made range-aware; that is, they should have constructors and insert and append member functions that accept range arguments. These things can be done in a separate proposal.

#### C.10 Verbosity in Algorithm Constraints

[future.constraints]

<sup>1</sup> The constraints of some of the algorithms are verbose. Some composite concepts exist that group constraints together to increase uniformity, aid comprehensibility, and reduce verbosity for those algorithms that use

them. See Sortable, Mergeable, and Permutable, for instance. There may be other useful clusters of concepts for other algorithm groups. Finding them and using them to improve the algorithm constraints is an important work item.
